CONTENTS

FORMAL LANGUAGES AND AUTOMATA THEORY

Objectives:

- To teach the student to identify different formal language classes and their relationships
- To teach the student the theoretical foundation for designing compilers.
- To teach the student to use the ability of applying logical skills.
- Teach the student to prove or disprove theorems in automata theory using its properties
- To teach the student the techniques for information processing.
- Understand the theory behind engineering applications.

UNIT I:

Fundamentals: Strings, Alphabet, Language, Operations, Finite state machine, definitions, finite automaton model, acceptance of strings, and languages, FA, transition diagrams and Language recognizers.

Finite Automata: Deterministic finite automaton, Non deterministic finite automaton and NFA with ϵ transitions - Significance, acceptance of languages. Conversions and Equivalence : Equivalence between NFA with and without ϵ transitions, NFA to DFA conversion, minimization of FSM, equivalence between two FSMs, Finite Automata with output- Moore and Melay machines.

UNIT II:

Regular Languages: Regular sets, regular expressions, identity rules, Conversion finite Automata for a given regular expressions, Conversion of Finite Automata to Regular expressions. Pumping lemma of regular sets, closure properties of regular sets **(proofs not required).**

UNIT III:

Grammar Formalism: Regular grammars-right linear and left linear grammars, equivalence between regular linear grammar and FA, inter conversion, Context free grammar, derivation trees, sentential forms. Right most and leftmost derivation of strings.

Context Free Grammars: Ambiguity in context free grammars. Minimisation of Context Free Grammars. Chomsky normal form, Greibach normal form, Pumping Lemma for Context Free Languages. Enumeration of properties of CFL **(proofs omitted).**

UNIT IV:

Push Down Automata: Push down automata, definition, model, acceptance of CFL, Acceptance by final state and acceptance by empty state and its equivalence. Equivalence of CFL and PDA, interconversion. **(Proofs not required)**. Introduction to DCFL and DPDA. LINEAR BOUNDED AUTOMATA(LBA):LBA,context sensitive grammars ,CS languages

UNIT V:

Turing Machine: Turing Machine, definition, model, design of TM, Computable functions, recursively enumerable languages. Church's hypothesis, counter machine, types of Turing machines (proofs not required).

Computability Theory: Chomsky hierarchy of languages, linear bounded automata and context sensitive language, LR(0) grammar, decidability of, problems, Universal Turing Machine, undecidability of posts. Correspondence problem, Turing reducibility, Definition of P and NP problems, NP complete and NP hard problems.

TEXT BOOKS:

1. "Introduction to Automata Theory Languages and Computation". Hopcroft H.E. and Ullman J. D. Pearson Education.
2. Introduction to Theory of Computation - Sipser 2nd edition Thomson

REFERENCE BOOKS:

1. Introduction to Computer Theory, Daniel I.A. Cohen, John Wiley.
2. Introduction to languages and the Theory of Computation ,John C Martin, TMH
3. "Elements of Theory of Computation", Lewis H.P. & Papadimition C.H. Pearson /PHI.
4. Theory of Computer Science and Automata languages and computation -Mishra and Chandrashekaran, 2nd edition, PHI.
5. Theory of Computation, By K.V.N. Sunitha and N.Kalyani

Course Outcomes:

Student will have the ability to

- Apply knowledge in designing or enhancing compilers.
- Design grammars and automata (recognizers) for different language classes.
- Apply knowledge in developing tools for language processing or text processing.

CMR COLLEGE OF ENGINEERING & TECHNOLOGY

(AUTONOMOUS)

B.Tech V Semester Mid-II Examinations December -2023

(Regulation: CMRCET-R18)

Subject Name: Formal Languages& Automata Theory **Time: 1.30 PM to 3.10 PM**

Date:27-12-2023 **Branch: CSE** **Max Marks: 25**

PART A

Answer all FIVE questions (Compulsory)
Each question carries TWO marks. **5x2=10M**

Question Number	Question Format	CO	B.T Level
1	Differentiate TM and PDA	CO3	L2
2	Simplify or reduce the given CFG $S \rightarrow XYX$, $X \rightarrow 0X \mid \varepsilon$, $Y \rightarrow 1Y \mid \varepsilon$	CO4	L2
3	Show whether the language $\mathbf{L = \{x^n y^n z^n \mid n \geq 1\}}$ is context free or not	CO4	L1
4	Differentiate decidable and undecidable language with example	CO5	L2
5	Solve the PCP A=[aa, bb, abb] and B=[aab, ba, b]	CO5	L1

PART B

Answer ALL questions.
Each question carries FIVE Marks. **3x5=15M**

Question Number	Question Format	CO	B.T Level
6. A.	Construct PDA for the $L=\{a^n b^{2n} / n>=1\}$	CO3	L2
	OR		
6. B.	Construct a PDA equivalent to the following context free grammar S->0BB,B->0S|1S|0 Show the acceptance for the input string 010000 by PDA	CO3	L6
7. A.	Find a grammar in Chomsky normal form equivalent to S → aAbB, A→aA|a , B-> bB|b.	CO4	L2
	OR		
7. B.	Find a reduced grammar equivalent to the grammar G whose productions are S-> AB | CA, B-> BC |AB, A-> a C->aB|b	CO4	L2
8. A.	a) Describe the types of Turing machines	CO5	L2

8. **B.**	b) Show that the PCP with two lists A=(b, bab^3,ba) and B=(b^3,ba,a) has a solution .and give solution sequence OR a)Explain recursive enumerable languages. b) Explain decidable and undecidable languages.	**CO5**	**L1**

Hall Ticket No.

Question Paper Code: A30518

CMR COLLEGE OF ENGINEERING & TECHNOLOGY

(AUTONOMOUS)

B.Tech V Semester Mid-II Examinations December -2023

(Regulation: CMRCET-R18)

Subject Name: : Formal Languages& Automata Theory **Time: 1.30 PM to 3.10 PM**

Date: 27-12-2023 **Branch: CSE** **Max Marks: 25**

PART A

Answer all FIVE questions (Compulsory)

Each question carries TWO marks. **5x2=10M**

Question Number	Question Format	CO	B.T Level
1	Define PDA and draw its model?	CO3	L1
2	List out rules to construct CNF and GNF	CO4	L2
3	Apply CNF for the given CFG S->bA/aB, A->Baa/aS/a, B->aBB/bS/b	CO4	L3
4	Identify the languages and recognizers by using Chomsky hierarchy?	CO5	L1
5	List out the properties recursive enumerable language?	CO5	L1

PART B

Answer ALL questions.

Each question carries FIVE Marks. **3x5=15M**

Question Number	Question Format	CO	B.T Level
6A	Design PDA to recognize the language $\{a^n b^n / n>=1\}$	CO3	L6
	OR		
6B	Construct a pda A equivalent to the following context-free grammar: S-> 0BB. B-> 0S|1S| 0. Test whether the string accepted by 010^4.	CO3	L6
7A	Define Griebach Normal form? Convert the following CFG into GNF. S->AA|a A->SS/b	CO4	L1
	OR		
7B	Find a grammar in Chomsky normal form equivalent to S -> aAbB, A-> Aa | B-> bB |b.	CO4	L3
8A	Explain Recursive and recursive enumerable language in details?	CO5	L1
	OR		
8B	Design Turing Machine to recognize the language $\{a^n b^n c^n / n>=1\}$	CO5	L6

MID SEMESTER EXAMINATION ANSWER BOOK

Registered No. 2 1 H 5 1 A 0 5 2 4

FIRST / SECOND SEMESTER EXAMINATION B.Tech./M.Tech./MBA III V Semester 12/2023
(Month and year)

Subject : Formal language and Automata Theory

Date : 27/12/2023

27/12/23
Signature of the Invigilator with date

INSTRUCTIONS TO THE CANDIDATES

1. This booklet contains 16 pages. Candidates must ensure it before writing and in case a defective answer book is issued it must be returned to the invigilator and a new and defect free booklet must be obtained.
2. Before the candidate begins to answer, registered number, particulars of year, semester, subject etc., are to be filled in. Failure to enter all or any of these particulars may disqualify the paper from valuation.
3. Candidate is prohibited from
   (a) Writing.
   - ☞ anything addressing the examiner in any manner whatsoever, in their answer book.
   - ☞ Objectionable/obscene language in the answer book.
   - ☞ anything other than their Registered Number on the question paper.

   (b) either seeking or providing any assistance to the fellow candidates in the exam.
   (c) possessing a manuscript or a printed matter, in any form, in the examination hall.
   (d) bringing loose sheets or paper into the examination hall and detaching any paper from the answer book.
   (e) carrying Mobile Phone to Exam Hall.

   Violation of these instructions will be viewed as a case of malpractice, which is a punishable offence.
4. Before beginning to answer any question, candidates must write the correct question number, in the margin only and should not write anything else in the margin.
5. Answers must be written legibly on both sides of the paper. There shall be about 25 lines in each page. It is not necessary to begin each answer on a fresh page. Candidates should not use any other ink, except BLACK or BLUE ink.
6. Rough work, if any, must be separated, from the subject matter, by a line and noted as rough work.
7. The answer book, at the end of the examination, must be handed over to the Assistant Superintendent (Invigilator) by the candidate **This responsibility lies with the candidate only.**
8. Candidates should maintain absolute silence during the time of examination. Misbehavior, in any form, by the candidate, in the examination hall, will attract severe punishment.
9. Candidates are permitted to leave the examination hall only after the expiry of half of the allotted time and candidates will be permitted to carry the question paper only when they are leaving the exam hall in the last half-an-hour.
10. **No additional answer books will be supplied.**

To be filled in by the Examiner only

PART-B

6A) $L = \{a^n b^n / n >= 1\}$

$n = \{1, 2, 3\}$

$L = \{a^1 b^1, a^2 b^2, a^3 b^3 \dots\}$

$L = \{ab, aabb, aaabbb \dots\}$

$W = aabb$

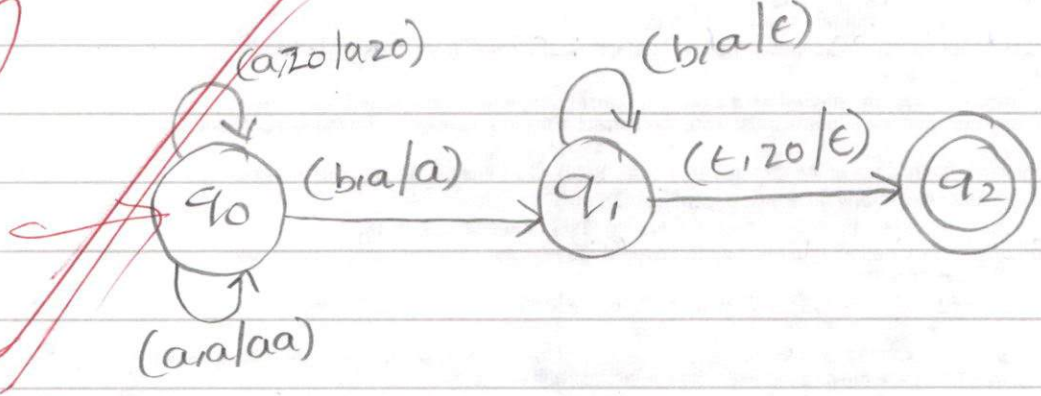
$(q_0, a, z_0) = (q_0, az_0)$

$(q_0, a, az_0) = (q_0, aa)$

$(q_0, b, aa) = (q_1, a)$

$(q_1, b, a) = (q_1, \epsilon)$

$(q_1, \epsilon, z_0) = (q_2, \epsilon)$



7A) Girebach Normal form:-

It can be represented as context free Grammar

Non Terminal → Terminal · Any no. of NON Ter

Ex:

$A \rightarrow a$ [GNF]

$A \rightarrow aTT$ [GNF]

$A \rightarrow Taa$ [Not in GNF]

~~Given S → aAbB~~

~~A → Aa~~

~~B → bB/b~~

Given S → AA/a

A → ss/b

Now, Rule 1:- A → ss/b (S value sub in A → ss/b)

A → AAS/as/b

α_1 β_1 β_2

Rule 2:-

$A = \beta_1 B / \beta_2 B \text{ --- } \beta_n B / \beta_1 / \beta_2 \text{ --- } \beta_n$

$B = \alpha_1 B / \alpha_2 B \text{ --- } \alpha_n B / \alpha_1 / \alpha_2 \text{ --- } \alpha_n$

A = asB/bB/as/b [GNF]

B = ASB/AS now substitute A value in B

B = aSBSB/bBSB/asSB/bSB/aSBS/bBS/ass/bS [GNF]

Now

S → AA/a (sub A value in S → AA/a)

S = aSBA/bBA/asA/bA/a [GNF].

8B) $L = \{a^n b^n c^n / n >= 1\}$

$n = \{1, 2, 3, 4 \text{ ---} \}$

$L = \{a^1 b^1 c^n, a^2 b^2 c^2, a^3 b^3 c^3 \text{ ---} \}$

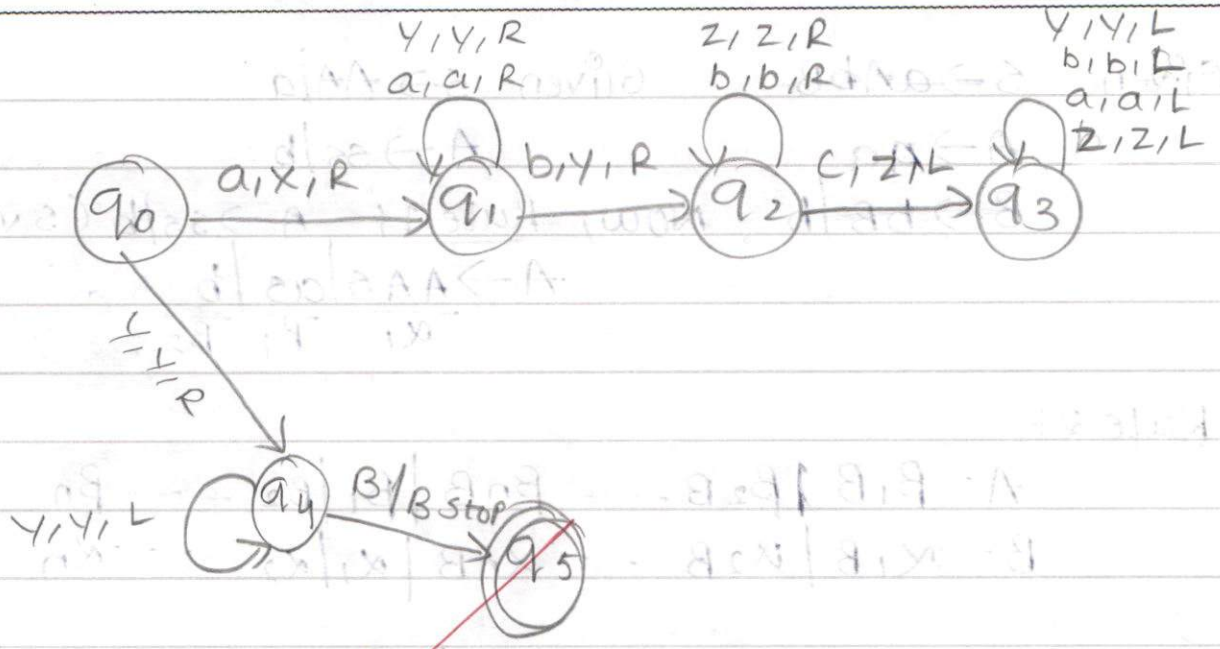
$L = \{abc, aabbcc, aaabbbccc \text{ ---} \}$

w = aaabbbccc

XaaYbbZcc

XXaYYbZZc

Step 1:- Replace 'a' with X and move right side. Turing meachine can move to any side and it has infinite memory and remembers previous data also.



step2 :- Replace 'a' by b.
step3 :- Replace 'z' by c and till x.
step4 :- After seeing 'x' replace a by x and do some loop.
step5 :- Next move 'b' replace by y
step6 :- move to z and finish loop. one by other first and after do looping then turing meachine is succeded.

To construct a diagram by self loop we have mainly two steps:

Xaabbzcc

XXayybzzc.

we have to read in between symbols to get self looping

GROUP OF INSTITUTIONS
EXPLORE TO INVENT

PART-A

(1) PDA → Push Down Automata

It can be reprsented as finite Automata and it consists of 7 tuples $(Q, \Sigma, q_0, F, \delta, Z_0, \Gamma)$

where $Q \rightarrow$ No. of states

$\Sigma \rightarrow$ Input set

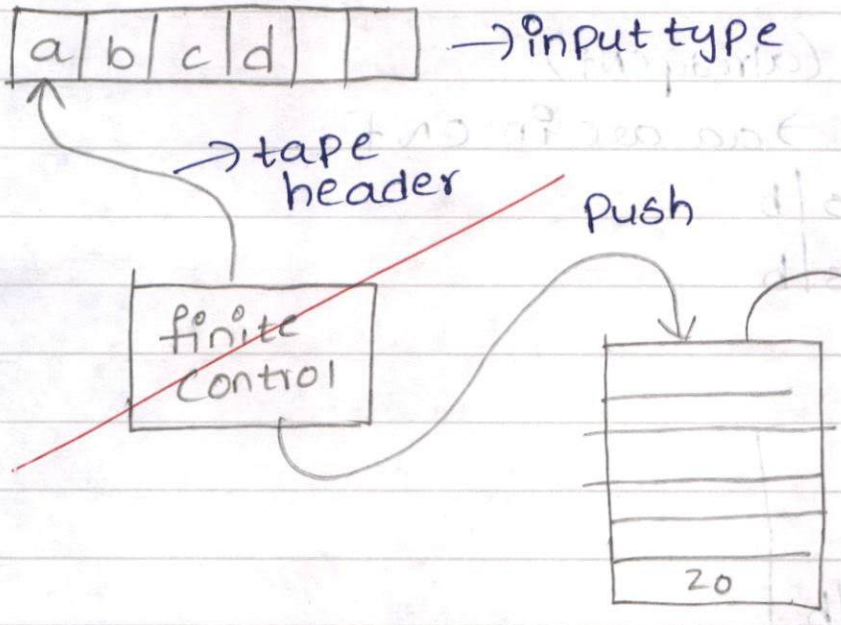
$q_0 \rightarrow$ Initial state

$F \rightarrow$ final state

$\delta \rightarrow$ transition / mapping

$Z_0 \rightarrow$ Top of the stack

$\Gamma \rightarrow$ no. of / set of values in the stack



(2) Rules to construct CNF and GNF:-

1) The grammar should in CNF, if the grammar is not in CNF first convert it into CNF.

2) If the grammar exists in left recursion, then eliminate it.

3) ~~If the~~ grammar ~~should~~ production line should be in

GNF, if it is not in GNF, then given input grammar is converted to production line in GNF.

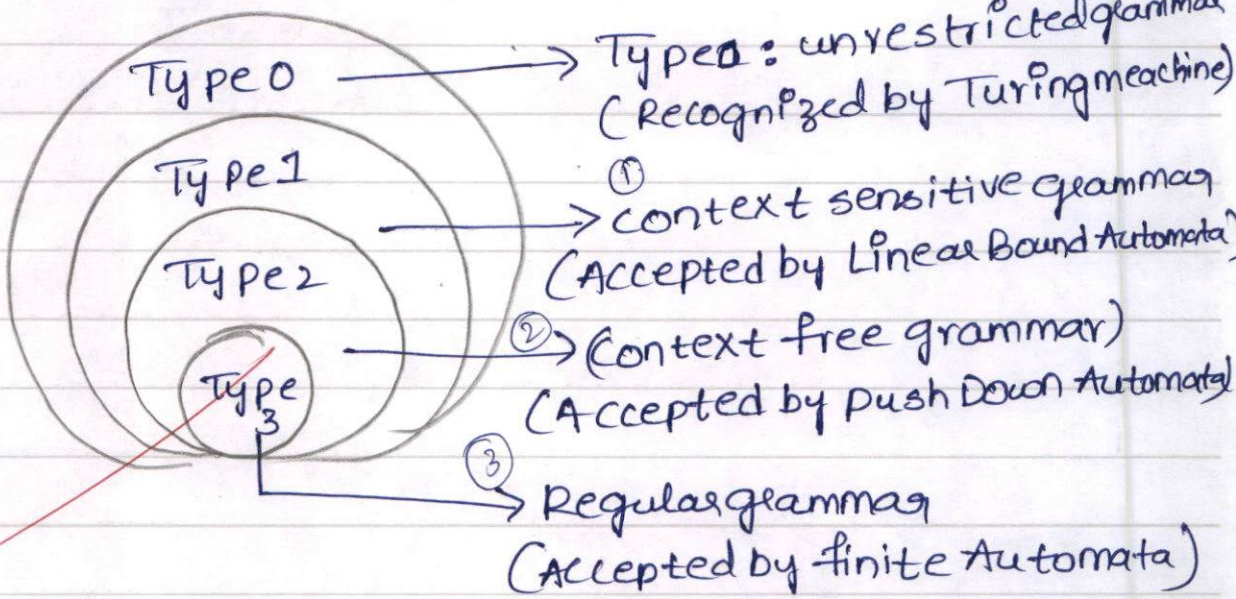
③ $S \to bA/aB$
$A \to Baa/as/a$
$B \to aBB/bs/b$

NOW,
$A \to as/a$
$B \to bs/b$
~~$A \to Baa$~~
$A \to BA$ ✓
$A \to aa$ ✓
$S \to bA/aB$ ✓ (already CNF)
$A \to BA$ and $A \to aa$ are in CNF
$B \to aBB/bs/b$
$B \to aBC/bs/b$
$C \to B$

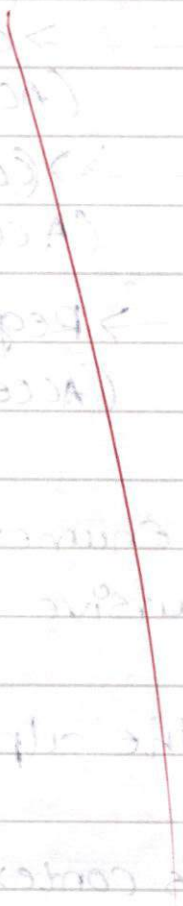
CNF

$S \to bA/aB$
$A \to BC/as/a$
$B \to aBC/bs/b$
$A \to aa$
$C \to B$

(4) The chomsky hierarchy is divided into 4 divisions:
1) Type 0 is known as unrestricted grammar.
2) Type 1 is known as context sensitive grammar.
3) Type 2 is known as context free grammar.
4) Type 3 is known as Regular grammar.



(5) Properties of recursive enumerable language:
(1) The complement of recursive enumerable language is recursive.
(2) The strings all over the alphabets is countable.
(3) If the language 'L' is context free grammar then its complement is not context free grammar.



Rough

CFG → NonTe → NonTe · NonTe

S → bA/aB

EXPLORE TO INVENT

PART-A

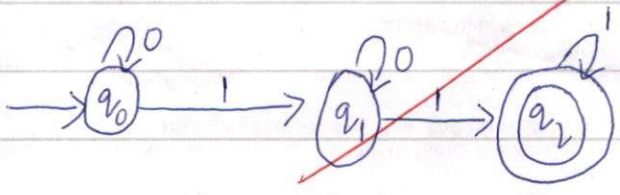
1) Finite Automata:

Finite Autometa consists of regular expressions and converts the expression into the regular language.

There are two types of Finite Autometa. They are:

1) Deterministic Finite Autometa (DFA)
2) Non-Deterministic Finite Autometa (NDFA)

2) NFA to accept a set of all strings that do not contain two consecutive zeros is



In this NFA design, there are no two consecutive zeros.

3) Regular Expression:

A set of strings which consists in an algebraic function is called as Regular Expression.

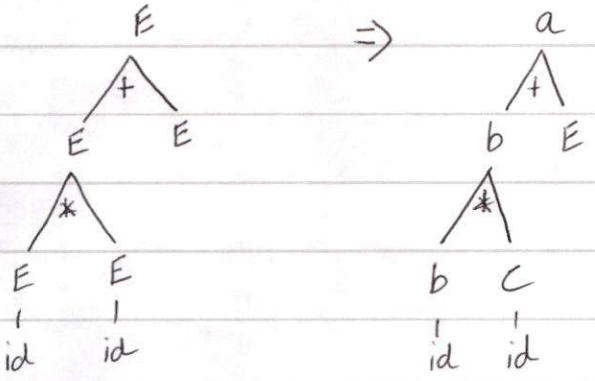
Applications:

-> It is used in conversion of regular languages.
-> It is used in Parse Tree construction.
-> Union, Intersection, concatination are the properties of regular expressions.

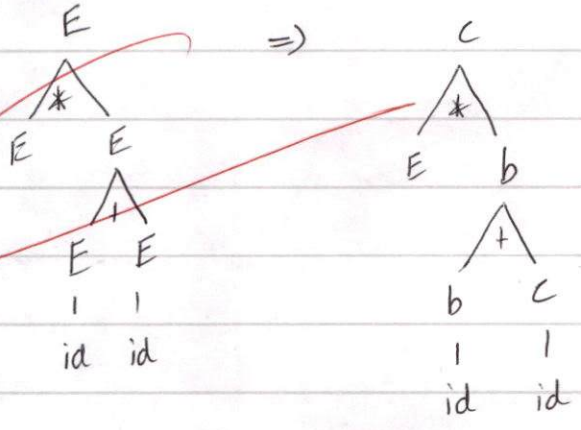
4) Given,

$a + b * c$, $E \rightarrow E + E \mid E * E \mid a \mid b \mid c$.

Left Most Derivative Tree



Right Most Derivative Tree



5) Arden's Theorem:

→ The expression of finite automata is written in a way such that there are variables as 'P' and 'R' and 'Q'.

Arden's Theorm state that

$$R = Q + RP$$

where

$$\boxed{R = QP^*}$$

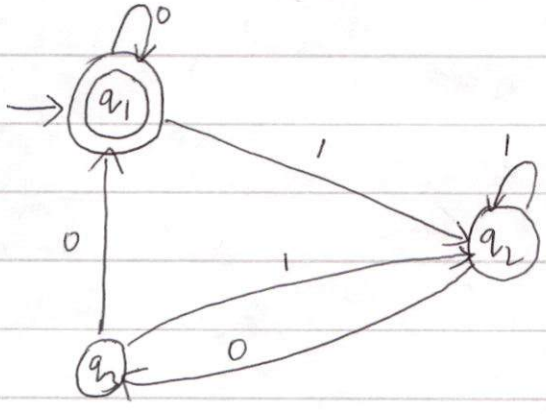
Closure properties of regular languages are

1) Union Property
2) Intersection Property
3) Concatination Property
4) Klenne Closure Property

PART-B

8. B) Finite Autometa → Regular Expression.

Given,



$q_1 = \epsilon + q_1 0 + q_3 0$ — (1) [∵ ϵ is added because it is in initial state]

$q_2 = q_1 0 + q_2 1 + q_3 1$ — (2)

$q_3 = q_2 0$ — (3)

By Substituting (3) in (2) we get,

$q_2 = q_1 0 + q_2 1 + q_2 01$

$q_2 = q_1 0 + q_2 (01 + 1)$ [∵ q_2 taking common]

By arden's Theorm we know that,

$R = Q + RP$

$R = QP^*$

$\therefore q_2 = q_1 0 + q_2 (1+01)$

$\downarrow \quad \downarrow \quad \downarrow$

$Q \quad R \quad P$

$\therefore \boxed{q_2 = q_1 0 (1+01)^*} \quad - (4)$

Now substituting (4) in (5) we get q_3.

$q_3 = q_2 0$

$\boxed{q_3 = q_1 0 (1+01)^* 0} \quad - (5)$

To find q_1 we have to substitute (4), (5) in (1), we get,

$q_1 = \varepsilon + q_1 0 + q_3 0$

$q_1 = \varepsilon + q_1 0 + q_1 0 (1+01)^* 0$

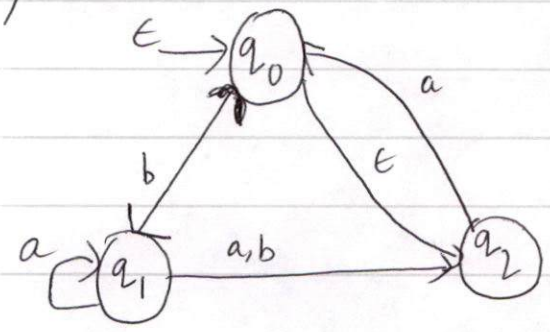
$q_1 = \varepsilon + q_1 (0 + (1+01)^* 00) \quad [\because R = q_1, Q = \varepsilon, P = (0 + (1+01)^* 00)]$.

It is in the form of arden's Theorm, $R = QP^*$

$\therefore q_1 = \varepsilon (0 + (1+01)^* 00)^*$

$\boxed{\therefore q_1 = (0 + (1+01)^* 00)^*}$ is the regular expression.

7. A) Given, NFA



ϵ-closure of $q_0 = \{q_0, q_2\}$
ϵ-closure of $q_1 = \{q_1\}$
ϵ-closure of $q_2 = \{q_2\}$

$$\delta'(q, a) = \epsilon\text{-closure}\left(\delta(\hat{\delta}(q, \epsilon)), a\right)$$

$$\hat{\delta}(q, \epsilon) = \epsilon\text{-closure}(q)$$

By substituting all the states in the above formula, we get.

$$\begin{aligned}
\delta'(q_0, a) &= \epsilon\text{-closure}\left(\delta(\hat{\delta}(q_0, \epsilon)), a\right) \\
&= \epsilon\text{-closure}\left(\delta(\epsilon\text{-closure}(q_0)), a\right) \\
&= \epsilon\text{-closure}\left(\delta(q_0, q_2), a\right) \\
&= \epsilon\text{-closure}\left(\delta(q_0, a) \cup \delta(q_2, a)\right) \\
&= \epsilon\text{-closure}\left(\phi \cup q_0\right) \\
&= \epsilon\text{-closure}(q_0)
\end{aligned}$$

$$\boxed{\delta'(q_0, a) = \{q_0, q_2\}}$$

$\delta'(q_0, b) = \epsilon\text{-closure}(\delta(\hat{\delta}(q_0, \epsilon), b)$

$= \epsilon\text{-closure}(\delta(q_0, q_2), b)$

$= \epsilon\text{-closure}(\delta(q_0, b) \cup \delta(q_2, b))$

$= \epsilon\text{-closure}(q_1 \cup \phi)$

$= \epsilon\text{-closure}(q_1)$

$\boxed{\delta'(q_0, b) = \{q_1\}}$

$\delta'(q_1, a) = \epsilon\text{-closure}(\delta(\hat{\delta}(q_1, \epsilon), a)$

$= \epsilon\text{-closure}(\delta(q_1), a)$

$= \epsilon\text{-closure}(q_1 q_2)$

$\boxed{\delta'(q_1, a) = \phi}$

$\delta'(q_1, b) = \epsilon\text{-closure}(\delta(\hat{\delta}(q_1, \epsilon), b)$

$= \epsilon\text{-closure}(\delta(q_1), b)$

$= \epsilon\text{-closure}(q_2)$

$\boxed{\delta'(q_1, b) = \{q_2\}}$

$\delta'(q_2, a) = \epsilon\text{-closure}(\delta(\hat{\delta}(q_2, \epsilon)), a)$

$= \epsilon\text{-closure}(\delta(q_2), a)$

$= \epsilon\text{-closure}(q_0)$

$\boxed{\delta'(q_2, a) = \{q_0, q_2\}}$

$\delta'(q_2, b) = \epsilon\text{-closure}(\delta(\hat{\delta}(q_2, \epsilon), b)$

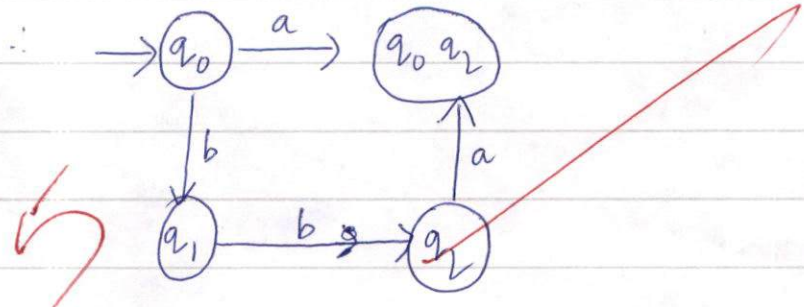
$= \epsilon\text{-closure}(\delta(q_2), b)$

$= \epsilon\text{-closure}(\phi)$

$\boxed{\delta'(q_2, b) = \phi}$

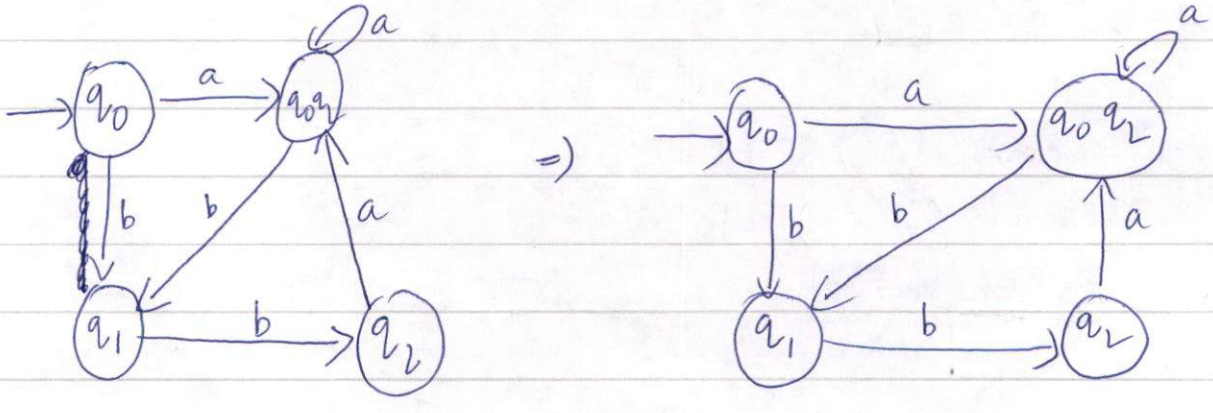
Transition Table:

state \ Input	a	b
q_0	$\{q_0, q_2\}$	$\{q_1\}$
q_1	ϕ	$\{q_2\}$
q_2	$\{q_0, q_2\}$	ϕ



DFA:

state \ Input	a	b
q_0	$q_0 q_2$	q_1
$q_0 q_2$	$q_0 q_2$	q_1
q_1	-	q_2
q_2	$q_0 q_2$	-



∴ This was the construction of DFA from NFA.

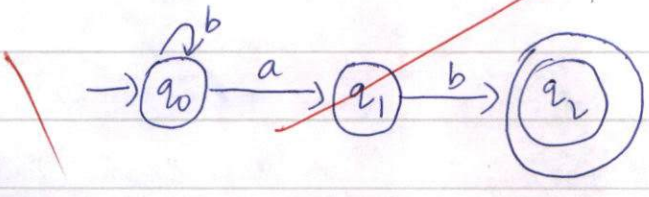
6. A) i)

NFA	DFA
i) It is non-deterministic	i) DFA is deterministic
ii) NFA does not allow back tracking	ii) DFA allows back Tracking
iii) Less space is required	iii) It takes more space
iv) Empty regions are allowed	iv) Empty spaces are not seen in DFA
v) Final state is not there in NFA	v) Final state is must done in DFA.

These are the differences between NFA and DFA.

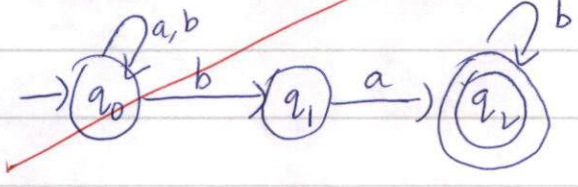
ii) i) exactly one a

$D(\Sigma, \delta, a, R)$



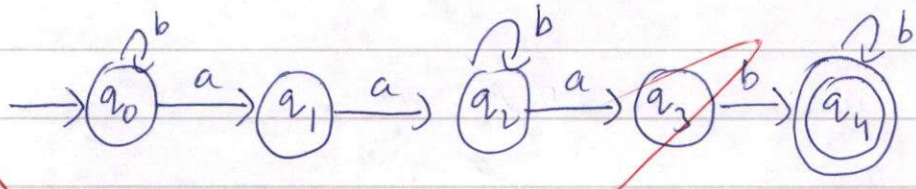
In this DFA design only 1 'a' is allowed.

ii) atleast one 'a'



CMR
GROUP OF INSTITUTIONS
EXPLORE TO INVENT

iii) Not more than 3 a's :



∴ These are the design's of DFA to accept the strings given.

NOTES ON
FORMAL LANGUAGES AND AUTOMATA THEORY

B.TECH III YEAR - I SEM
(2023-24)

DEPARTMENT OF CSE
CMRCET

INDEX

After going through this chapter, you should be able to understand :

- Alphabets, Strings and Languages
- Mathematical Induction
- Finite Automata
- Equivalence of NFA and DFA
- NFA with ϵ - moves

1.1 ALPHABETS, STRINGS & LANGUAGES

Alphabet

An alphabet, denoted by Σ, is a finite and nonempty set of symbols.

Example:

1. If Σ is an alphabet containing all the 26 characters used in English language, then Σ is finite and nonempty set, and $\Sigma = \{a, b, c, \ldots, z\}$.
2. $X = \{0,1\}$ is an alphabet.
3. $Y = \{1,2,3,\ldots\}$ is not an alphabet because it is infinite.
4. $Z = \{\}$ is not an alphabet because it is empty.

String

A string is a finite sequence of symbols from some alphabet.

Example :

"*xyz*" is a string over an alphabet $\Sigma = \{a, b, c, \ldots, z\}$. The empty string or null string is denoted by ϵ.

Length of a string

The length of a string is the number of symbols in that string. If w is a string then its length is denoted by $|w|$.

Example :

1. $w=abcd$, then length of w is $|w|= 4$
2. $n = 010$ is a string, then $|n| = 3$
3. ϵ is the empty string and has length zero.

The set of strings of length K (K ≥ 1)

Let Σ be an alphabet and $\Sigma = \{a, b\}$, then all strings of length K ($K \geq 1$) is denoted by Σ^K.

$\Sigma^K = \{w : w \text{ is a string of length } K, K \geq 1\}$

Example:

1. $\Sigma = \{a,b\}$, then

   $\Sigma^1 = \{a,b\}$,

   $\Sigma^2 = \{aa, ab, ba, bb\}$,

   $\Sigma^3 = \{aaa, aab, aba, abb, baa, bab, bba, bbb\}$

   $|\Sigma^1| = 2 = 2^1$ (Number of strings of length one),

   $|\Sigma^2| = 4 = 2^2$ (Number of strings of length two), and

   $|\Sigma^3| = 8 = 2^3$ (Number of strings of length three)
2. $S = \{0,1,2\}$, then $S^2 = \{00,01,02,11, 10,12,22,20,21\}$, and $|S^2| = 9 = 3^2$

Concatenation of strings

If w_1 and w_2 are two strings then concatenation of w_2 with w_1 is a string and it is denoted by w_1w_2. In other words, we can say that w_1 is followed by w_2 and $|w_1w_2| = |w_1| + |w_2|$.

Prefix of a string

A string obtained by removing zero or more trailing symbols is called prefix. For example, if a string $w = abc$, then a, ab, abc are prefixes of w.

Suffix of a string

A string obtained by removing zero or more leading symbols is called suffix. For example, if a string $w = abc$, then c, bc, abc are suffixes of w.
A string a is a proper prefix or suffix of a string w if and only if $a \neq w$.

Substrings of a string

A string obtained by removing a prefix and a suffix from string w is called substring of w. For example, if a string $w = abc$, then b is a substring of w. Every prefix and suffix of string w is a substring of w, but not every substring of w is a prefix or suffix of w. For every string w, both w and ϵ are prefixes, suffixes, and substrings of w.
Substring of w = w – (one prefix) – (one suffix).

Language

A Language L over Σ, *is a subset of* Σ^*, *i. e., it is a collection of strings over the alphabet* Σ. ϕ, and $\{\epsilon\}$ are languages. The language ϕ is undefined as similar to infinity and $\{\epsilon\}$ is similar to an empty box i.e. a language without any string.

Example:

1. $L_1 = \{01, 0011, 000111\}$ is a language over alphabet $\{0,1\}$
2. $L_2 = \{\epsilon, 0, 00, 000, ...\}$ is a language over alphabet $\{0\}$
3. $L_3 = \{0^n 1^n 2^n : n \geq 1\}$ is a language.

Kleene Closure of a Language

Let L be a language over some alphabet Σ. Then Kleene closure of L is denoted by L^* and it is also known as reflexive transitive closure, and defined as follows :

L^* = {*Set of all words over* Σ}

= {word of length zero, words of length one, words of length two, ...}

$= \bigcup_{K=0}^{\infty} (\Sigma^K) = L^0 \cup L^1 \cup L^2 \cup \ldots$

Example:

1. $\Sigma = \{a, b\}$ and a language L over Σ. Then

   $L^* = L^0 \cup L^1 \cup L^2 \cup \ldots$

   $L^0 = \{\in\}$

   $L^1 = \{a, b\}$,

   $L^2 = \{aa, ab, ba, bb\}$ and so on.

   So, $L^* = \{\in, a, b, aa, ab, ba, bb \ldots\}$

2. $S = \{0\}$, then $S^* = \{\in, 0, 00, 000, 0000, 00000, \ldots\}$

Positive Closure

If Σ is an alphabet then positive closure of Σ is denoted by Σ^+ and defined as follows :

$\Sigma^+ = \Sigma^* - \{\in\}$ = {*Set of all words over* Σ *excluding empty string* $\in$}

Example :

if $\Sigma = \{0\}$, then $\Sigma^+ = \{0, 00, 000, 0000, 00000, \ldots\}$

1. 2 MATHEMATICAL INDUCTION

Based on general observations specific truths can be identified by reasoning. This principle is called mathematical induction. The proof by mathematical induction involves four steps.

Basis : This is the starting point for an induction. Here, prove that the result is true for some n = 0 or 1.

Induction Hypothesis : Here, assume that the result is true for n = k.

Induction step : Prove that the result is true for some n = k + 1.

Proof of induction step : Actual proof.

1.3 FINITE AUTOMATA (FA)

A finite automata consists of a finite memory called input tape, a finite - nonempty set of states, an input alphabet, a read - only head , a transition function which defines the change of configuration, an initial state, and a finite - non empty set of final states.

A model of finite automata is shown in figure 1.1.

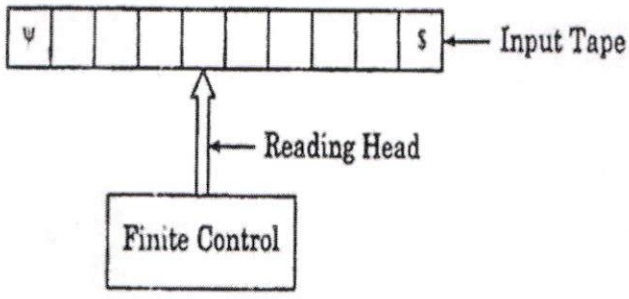


FIGURE 1.1 : Model of Finite Automata

The input tape is divided into cells and each cell contains one symbol from the input alphabet. The symbol 'ψ' is used at the leftmost cell and the symbol '$' is used at the rightmost cell to indicate the beginning and end of the input tape. The head reads one symbol on the input tape and finite control controls the next configuration. The head can read either from left - to - right or right - to -left one cell at a time. The head can't write and can't move backward. So , FA can't remember its previous read symbols. This is the major limitation of FA.

Deterministic Finite Automata (DFA)

A deterministic finite automata M can be described by 5 - tuple $(Q, \Sigma, \delta, q_0, F)$, where

1. Q is finite, nonempty set of states,
2. Σ is an input alphabet,
3. δ is transition function which maps $Q \times \Sigma \rightarrow Q$ i. e. the head reads a symbol in its present state and moves into next state.
4. $q_0 \in Q$, known as initial state
5. $F \subseteq Q$, known as set of final states.

Non - deterministic Finite Automata (NFA)

A non - deterministic finite automata M can be described by 5 - tuple $(Q, \Sigma, \delta, q_0, F)$, where

1. Q is finite, nonempty set of states,
2. Σ is an input alphabet,
3. δ is transition function which maps $Q \times \Sigma \rightarrow 2^Q$ i. e., the head reads a symbol in its present state and moves into the set of next state (s). 2^Q is power set of Q,
4. $q_0 \in Q$, known as initial state, and
5. $F \subseteq Q$, known as set of final states.

The difference between a DFA and a NFA is only in transition function. In DFA, transition function maps on at most one state and in NFA transition function maps on at least one state for a valid input symbol.

States of the FA

FA has following states :

1. **Initial state :** Initial state is an unique state ; from this state the processing starts.
2. **Final states :** These are special states in which if execution of input string is ended then execution is known as successful otherwise unsuccessful.
3. **Non - final states :** All states except final states are known as non - final states.
4. **Hang - states :** These are the states, which are not included into Q, and after reaching these states FA sits in idle situation. These have no outgoing edge. These states are generally denoted by ϕ. For example, consider a FA shown in figure1.2.

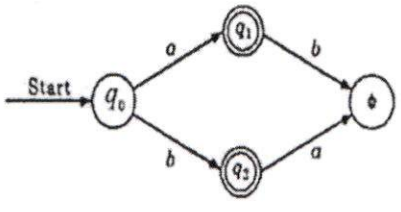

FIGURE 1.2 : Finite Automata

q_0 is the initial state, q_1, q_2 are final states, and ϕ is the hang state.

Notations used for representing FA

We represent a FA by describing all the five - terms $(Q, \Sigma, \delta, q_0, F)$. By using diagram to represent FA make things much clearer and readable. We use following notations for representing the FA:

1. The initial state is represented by a state within a circle and an arrow entering into circle as shown below:

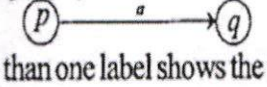
(Initial state q_0)

2. Final state is represented by final state within double circles:

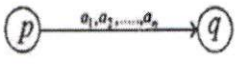
(Final state q_f)

3. The hang state is represented by the symbol 'ϕ' within a circle as follows:

4. Other states are represented by the state name within a circle.
5. A directed edge with label shows the transition (or move). Suppose p is the present state and q is the next state on input - symbol 'a', then this is represented by

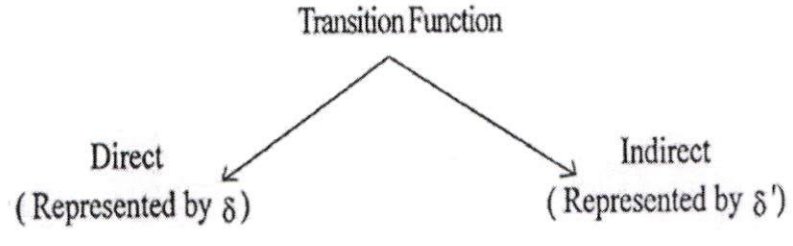


6. A directed edge with more than one label shows the transitions (or moves). Suppose p is the present state and q is the next state on input - symbols 'a_1' or 'a_2' or ... or 'a_n' then this is represented by



Transition Functions

We have two types of transition functions depending on the number of arguments.



Direct transition Function (δ)

When the input is a symbol, transition function is known as direct transition function.

Example : $\delta(p, a) = q$ (Where p is present state and q is the next state).

It is also known as one step transition.

Indirect transition function (δ')

When the input is a string, then transition function is known as indirect transition function.

Example : $\delta'(p, w) = q$, where p is the present state and q is the next state after | w | transitions. It is also known as one step or more than one step transition.

Properties of Transition Functions

1. If $\delta(p, a) = q$, then $\delta(p, ax) = \delta(q, x)$ and if $\delta'(p, x) = q$, then $\delta'(p, xa) = \delta'(q, a)$
2. For two strings x and y ; $\delta(p, xy) = \delta(\delta(p, x), y)$, and $\delta'(p, xy) = \delta'(\delta'(p, x), y)$

Example :1. A DFA $M = (\{q_0, q_1, q_2, q_f\}, \{0,1\}, \delta, q_0, \{q_f\})$ is shown in figure1.3.

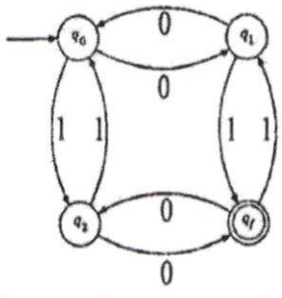


FIGURE 1.3 : Deterministic finite automata

Where δ is defined as follows :

	0	1
→ q_0	q_1	q_2
q_1	q_0	q_f
q_2	q_f	q_0
q_f	q_2	q_1

2. ANFA $M_1 = (\{q_0, q_1, q_2, q_f\}, \{0,1\}, \delta, q_0, \{q_f\})$ is shown in figure1.4.

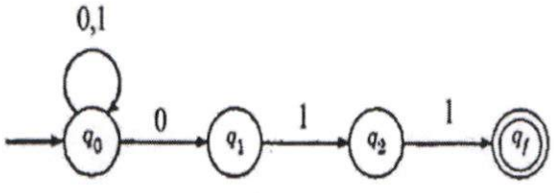

FIGURE 1.4 : Non - deterministic finite automata

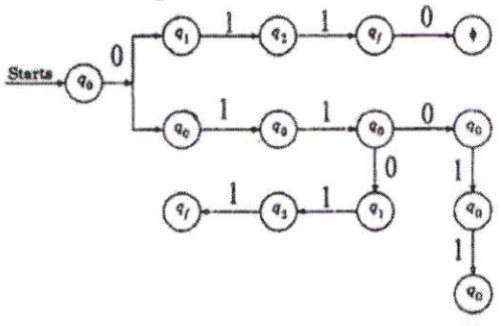
3. Transition sequence for the string "011011" is as follows :



One execution ends in hang state ϕ, second ends in non - final state q_0, and third ends in final state q_f hence string "011011" is accepted by third execution.

Difference between DFA and NFA

Strictly speaking the difference between DFA and NFA lies only in the definition of δ. Using this difference some more points can be derived and can be written as shown :

DFA	NFA
1. The DFA is 5 - tuple or quintuple $M = (Q, \Sigma, \delta, q_0, F)$ where Q is set of finite states Σ is set of input alphabets $\delta : Q \times \Sigma$ *to* Q q_0 is the initial state $F \subseteq Q$ is set of final states	The NFA is same as DFA except in the definition of δ. Here, δ is defined as follows : $\delta : Q \times (\Sigma \cup \in)$ to subset of 2^Q
2. There can be zero or one transition from a state on an input symbol	There can be zero, one or more transitions from a state on an input symbol
3. No $\in$ – transitions exist i.e., there should not be any transition or a transition if exist it should be on an input symbol	$\in$ – transitions can exist i. e., without any input there can be transition from one state to another state.
4. Difficult to construct	Easy to construct

The NFA accepts strings a, ab, abbb etc. by using ϵ path between q_1 and q_2 we can move from q_1 state to q_2 without reading any input symbol. To accept ab first we are moving from q_0 to q_1 reading a and we can jump to q_2 state without reading any symbol there we accept b and we are ending with final state so it is accepted.

Equivalence of NFA with ϵ- Transitions and NFA without ϵ- Transitions

Theorem : If the language L is accepted by an NFA with ϵ- transitions, then the language L_1 is accepted by an NFA without ϵ- transitions.

Proof : Consider an NFA 'N' with ϵ- transitions where $N=(Q, \Sigma, \delta, q_0, F)$

Construct an NFA N_1 without ϵ- transitions $N_1=(Q_1, \Sigma, \delta_1, q_0, F_1)$

where $Q_1 = Q$ and

$$F_1 = \begin{cases} F \cup \{q_0\} & \text{if } \epsilon\text{-closure}(q_0) \text{ contains a state of } F \\ F & \text{otherwise} \end{cases}$$

and $\delta_1(q,a)$ is $\hat{\delta}(q,a)$ for q in Q and a in Σ.

Consider a non - empty string ω. To show by induction $|\omega|$ that $\delta_1(q_0, \omega) = \hat{\delta}(q_0,\omega)$

For $\omega = \epsilon$, the above statement is not true. Because

$$\delta_1(q_0,\epsilon)=\{q_0\},$$

while $$\hat{\delta}(q_0,\epsilon)=\epsilon - closure\ (q_0)$$

Basis :

Start induction with string length one.

i.e., $|\omega|=1$

Then w is a symbol a, and $\delta_1(q_0,a)=\hat{\delta}(q_0,a)$ by definition of δ_1.

Induction : $|\omega|>1$

Let $\omega = xy$ for symbol a in Σ.

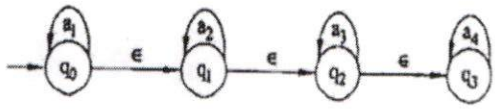
Then $\delta_1(q_0,xy)=\delta_1(\delta_1(q_0,x),y)$

Calculation of ϵ - closure :

ϵ - closure of state (ϵ-closure (q)) defined as it is a set of all vertices p such that there is a path from q to p labelled ϵ (including itself).

Example :

Consider the NFA with ϵ - moves



ϵ – closure $(q_0) = \{ q_0, q_1, q_2, q_3 \}$

ϵ – closure $(q_1) = \{ q_1, q_2, q_3 \}$

ϵ – closure $(q_2) = \{ q_2, q_3 \}$

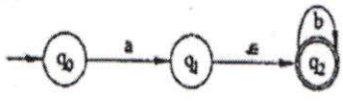
ϵ – closure $(q_3) = \{ q_3 \}$

Procedure to convert NFA with ϵ moves to NFA without ϵ moves

Let $N = (Q, \Sigma, \delta, q_0, F)$ is a NFA with ϵ moves then there exists $N' = (Q, \epsilon, \hat{\delta}, q_0, F')$ without ϵ moves

1. First find ϵ – closure of all states in the design.
2. Calculate extended transition function using following conversion formulae.
   (i) $\hat{\delta}(q, x) = \epsilon$ – closure $(\delta(\hat{\delta}(q, \epsilon), x))$
   (ii) $\hat{\delta}(q, \epsilon) = \epsilon$ – closure (q)
3. F' is a set of all states whose ϵ closure contains a final state in F.

Example 1 : Convert following NFA with ϵ moves to NFA without ϵ moves.



Solution : Transition table for given NFA is

δ	a	b	ϵ
$\rightarrow q_0$	q_1	ϕ	ϕ
q_1	ϕ	ϕ	q_2
(q_2)	ϕ	q_2	ϕ

(i) Finding $\in$ closure :

$\in$ – closure $(q_0) = \{q_0\}$

$\in$ – closure $(q_1) = \{q_1, q_2\}$

$\in$ – closure $(q_2) = \{q_2\}$

(ii) Extended Transition function :

$\hat{\delta}$	a	b
$\rightarrow q_0$	$\{q_1, q_2\}$	ϕ
(q_1)	ϕ	$\{q_2\}$
(q_2)	ϕ	$\{q_2\}$

$\hat{\delta}(q_0, a)$ $= \in$ *–closure* $(\delta(\hat{\delta}(q_0, \in), a))$

$= \in$ *–closure* $(\delta(\in$ *–closure* $(q_0), a))$

$= \in$ *–closure* $(\delta(q_0, a))$

$= \in$ *–closure* (q_1)

$= \{q_1, q_2\}$

$\hat{\delta}(q_0, b)$ $= \in$ *–closure* $(\delta(\hat{\delta}(q_0, \in), b))$

$= \in$ *– closure*$(\delta(\in$ *– closure* $(q_0), b))$

$= \in$ *– closure*$(\delta(q_0, b))$

$= \in$ *– closure*(ϕ)

$= \phi$

$\hat{\delta}(q_1, a)$ $= \in$ *– closure*$(\delta(\hat{\delta}(q_1, \in), a))$

$= \in$ *– closure*$(\delta(\in$ *– closure*$(q_1), a))$

$= \in$ *– closure*$(\delta((q_1, q_2), a))$

$= \in$ *– closure*$(\delta(q_1, a) \cup \delta(q_2, a))$

$= \in$ *– closure* (ϕ)

$= \phi$

$\hat{\delta}(q_1, b)$ $= \in - closure\ (\delta(\hat{\delta}(q_1, \in), b))$

$= \in - closure\ (\delta(\in - closure(q_1), b))$

$= \in - closure\ (\delta((q_1, q_2), b))$

$= \in - closure\ (\delta(q_1, b) \cup \delta(q_2, b))$

$= \in - closure\ (q_2)$

$= \{q_2\}$

$\hat{\delta}(q_2, a)$ $= \in - closure\ (\delta(\hat{\delta}(q_2, \in), a))$

$= \in - closure\ (\delta(\in - closure(q_2), a))$

$= \in - closure\ (\delta(q_2, a))$

$= \in - closure\ (\phi)$

$= \phi$

$\hat{\delta}(q_2, b)$ $= \in - closure\ (\delta(\hat{\delta}(q_2, \in), b))$

$= \in - closure\ (\delta(\in - closure(q_2), b))$

$= \in - closure\ (\delta(q_2, b))$

$= \in - closure\ (q_2)$

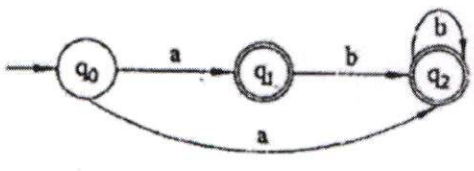
$= \{q_2\}$

(iii) Final states are q_1, q_2, because

$\in - closure\ (q_1)$ contains final state

$\in - closure\ (q_2)$ contains final state

(iv) NFA without $\in$ moves is



2.1 FINITE STATE MACHINES (FSMs)

A finite state machine is similar to finite automata having additional capability of outputs.

A model of finite state machine is shown in below figure.

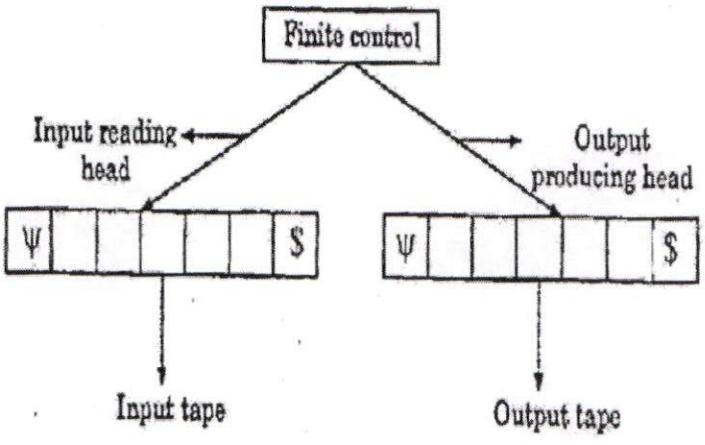


FIGURE : Model of FSM

2.1.1 Description of FSM

A finite state machine is represented by 6 - tuple $(Q,\Sigma,\Delta,\delta,\lambda,q_0)$, where

1. Q is finite and non - empty set of states,
2. Σ is input alphabet,
3. Δ is output alphabet,

4. δ is transition function which maps present state and input symbol on to the next state or $Q \times \Sigma \rightarrow Q$,
5. λ is the output function, and
6. $q_0 \in Q$, is the initial state.

2.1.2 Representation of FSM

We represent a finite state machine in two ways ; one is by transition table, and another is by transition diagram. In transition diagram, edges are labeled with Input / output.

Suppose, in transition table the entry is defined by a function F, so for input a_i and state q_i

$F(q_i, a_i) = (\delta(q_i, a_i), \lambda(q_i, a_i))$ (where δ is transition function, λ is output function.)

Example 1 : Consider a finite state machine, which changes 1's into 0's and 0's into 1's (1's complement) as shown in below figure.

Transition diagram :

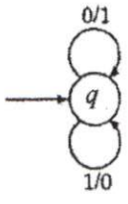

FIGURE : Finite state machine

Transition table :

Inputs				
	0		1	
Present State(PS)	Next State (NS)	Output	Next State (NS)	Output
q	q	1	q	0

Example 2 : Consider the finite state machine shown in below figure, which outputs the 2's complement of input binary number reading from least significant bit (LSB).

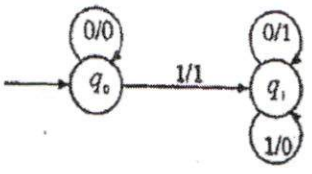

FIGURE : Finite State machine

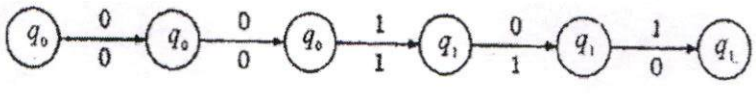
Suppose, input is 10100. What is the output ?

Solution : The finite state machine reads the input from right side (LSB).

Transition sequence for input 10100 :

Inputs ⟶



Outputs ⟶

So, the output is 01100.

2.2 MOORE MACHINE

If the *output of finite state machine is dependent on present state only,* then this model of finite state machine is known as Moore machine.

A Moore machine is represented by 6-tuple $(Q, \Sigma, \Delta, \delta, \lambda, q_0)$, where

1 Q is finite and non-empty set of states,

2 Σ is input alphabet,

3 Δ is output alphabet,

4 δ is transition function which maps present state and input symbol on to the next state or $Q \times \Sigma \rightarrow Q$,

5 λ is the output function which maps $Q \rightarrow \Delta$, (Present state $\rightarrow$ Output), and

6 $q_0 \in Q$, is the initial state.

If $Z(t), q(t)$ are output and present state respectively at time t then

$$Z(t) = \lambda(q(t)).$$

For input $\in$ (null string), $Z(t) = \lambda$ (initial state)

Consider three LSBs of	Input	Output
	...000 (X)	C
	...001 (X)	C
	...010 (X)	C
	...011 (X)	C
	...100 (X)	C
	...101	A
	...110	B
	...111 (X)	C

Transition diagram :

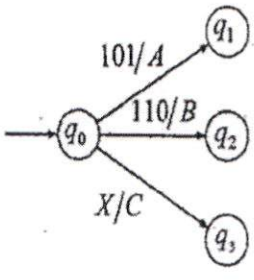


FIGURE : Moore Machine

2.4 EQUIVALENCE OF MOORE AND MEALY MACHINES

We can construct equivalent Mealy machine for a Moore machine and vice-versa. Let M_1 and M_2 be equivalent Moore and Mealy machines respectively. The two outputs $T_1(w)$ and $T_2(w)$ are produced by the machines M_1 and M_2 respectively for input string w. Then the length of $T_1(w)$ is one greater than the length of $T_2(w)$, i.e.

$$|T_1(w)| = |T_2(w)| + 1$$

The additional length is due to the output produced by initial state of Moore machine. Let output symbol x is the additional output produced by the initial state of Moore machine, then $T_1(w) = x\,T_2(w)$.

It means that if we neglect the one initial output produced by the initial state of Moore machine, then outputs produced by both machines are equivalent. *The additional output is produced by the initial state* of (for input ϵ) Moore machine without reading the input.

Conversion of Moore Machine to Mealy Machine

Theorem : If $M_1 = (Q, \Sigma, \Delta, \delta, \lambda, q_0)$ is a Moore machine then there exists a Mealy machine M_2 equivalent to M_1.

Proof : We will discuss proof in two steps.

Step 1 : Construction of equivalent Mealy machine M_2, and

Step 2 : Outputs produced by both machines are equivalent.

Step 1(Construction of equivalent Mealy machine M_2)

Let $M_2 = (Q, \Sigma, \Delta, \delta, \lambda', q_0)$ where all terms $Q, \Sigma, \Delta, \delta, q_0$ are same as for Moore machine and λ' is defined as following :

$$\lambda'(q, a) = \lambda(\delta(q, a)) \text{ for all } q \in Q \text{ and } a \in \Sigma$$

The first output produced by initial state of Moore machine is neglected and transition sequences remain unchanged.

Step 2 : If x is the output symbol produced by initial state of Moore machine M_1, and $T_1(w)$, $T_2(w)$ are outputs produced by Moore machine M_1 and equivalent Mealy machine M_2 respectively for input string w, then

$$T_1(w) = x T_2(w)$$

Or Output of Moore machine = x | | Output of Mealy machine

(The notation | | represents concatenation).

If we delete the output symbol x from $T_1(w)$ and suppose it is $T_1'(w)$ which is equivalent to the output of Mealy machine. So we have,

$$T_1'(w) = T_2(w)$$

Hence, Moore machine M_1 and Mealy machine M_2 are equivalent.

Example 1 : Construct a Mealy machine equivalent to Moore machine M_1 given in following transition table.

3. Δ remains unchanged,
4. λ' is defined as follows :

   $\delta'([q, b], a) = [\delta(q, a), \lambda(q, a)]$, where δ and λ are transition function and output function of Mealy machine.
5. λ' is the output function of equivalent Moore machine which is dependent on present state only and defined as follows :

$$\lambda'([q, b]) = b$$

6. q_0' is the initial state and defined as $[q_0, b_0]$, where q_0 is the initial state of Mealy machine and b_0 is any arbitrary symbol selected from output alphabet Δ.

Step 2 : Outputs of Mealy and Moore Machines

Suppose, Mealy machine M_1 enters states $q_0, q_1, q_2, \ldots q_n$ on input $a_1, a_2, a_3, \ldots . a_n$ and produces outputs $b_1, b_2, b_3, \ldots b_n$, then M_2 enters the states $[q_0, b_0], [q_1, b_1], [q_2, b_2] \ldots . , [q_n, b_n]$ and produces outputs $b_0, b_1, b_2, \ldots b_n$ as discussed in Step 1. Hence, outputs produced by both machines are equivalent.

Therefore, Mealy machine M_1 and Moore machine M_2 are equivalent.

Example 1 : Consider the Mealy machine shown in below figure. Construct an equivalent Moore machine.

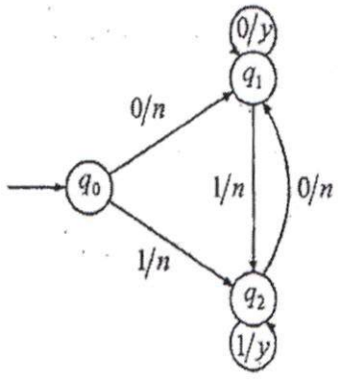

FIGURE : Mealy Machine

Solution : Let $M_1 = (Q, \Sigma, \Delta, \delta, \lambda, q_0)$ is a given Mealy machine and $M_2 = (Q', \Sigma, \Delta, \delta', \lambda', q_0')$ be the equivalent Moore machine,

where

1. $Q' \subseteq \{[q_0, n], [q_0, y], [q_1, n], [q_1, y], [q_2, n], [q_2, y]\}$ (Since, $Q' \subseteq Q \times \Delta$)
2. $\Sigma = \{0, 1\}$

3. $\Delta = \{n, y\}$,
4. $q_0' = [q_0, y]$, where q_0 is the initial state and y is the output symbol of Mealy machine,
5. δ' is defined as following :

For initial state $[q_0, y]$:

$$\delta'([q_0, y], 0) = [\delta(q_0, 0), \lambda(q_0, 0)] = [q_1, n]$$

$$\delta'([q_0, y], 1) = [\delta(q_0, 1), \lambda(q_0, 1)] = [q_2, n]$$

For state $[q_1, n]$:

$$\delta'([q_1, n], 0) = [\delta(q_1, 0), \lambda(q_1, 0)] = [q_1, y]$$

$$\delta'([q_1, n], 1) = [\delta(q_1, 1), \lambda(q_1, 1)] = [q_2, n]$$

For state $[q_2, n]$:

$$\delta'([q_2, n], 0) = [\delta(q_2, 0), \lambda(q_2, 0)] = [q_1, n]$$

$$\delta'([q_2, n], 1) = [\delta(q_2, 1), \lambda(q_2, 1)] = [q_2, y]$$

For state $[q_1, y]$:

$$\delta'([q_1, y], 0) = [\delta(q_1, 0), \lambda(q_1, 0)] = [q_1, y]$$

$$\delta'([q_1, y], 1) = [\delta(q_1, 1), \lambda(q_1, 1)] = [q_2, n]$$

For state $[q_2, y]$:

$$\delta'([q_2, y], 0) = [\delta(q_2, 0), \lambda(q_2, 0)] = [q_1, n]$$

$$\delta'([q_2, y], 1) = [\delta(q_2, 1), \lambda(q_2, 1)] = [q_2, y]$$

(Note : We have considered only those states, which are reachable from initial state)

6. λ' is defined as follows :

$$\lambda'[q_0, y] = y$$

$$\lambda'[q_1, n] = n$$

$$\lambda'[q_2, n] = n$$

$$\lambda'[q_1, y] = y$$

$$\lambda'[q_2, y] = y$$

2.5 EQUIVALENCE OF FSMs

Two finite machines are said to be equivalent if and only if every input sequence yields identical output sequence.

Example :

Consider the FSM M_1 shown in figure (a) and FSM M_2 shown in figure (b).

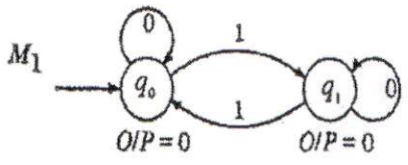

Figure (a)

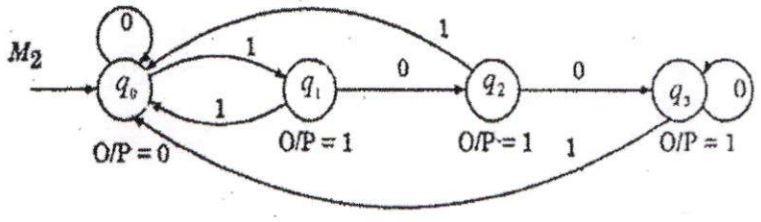

Figure (b)

Are these two FSMs equivalent ?

Solution :

We check this. Consider the input strings and corresponding outputs as given following :

Input string	Output by M_1	Output by M_2
(1) 01	00	00
(2) 010	001	001
(3) 0101	0011	0011
(4) 1000	0111	0111
(5) 10001	01111	01111

Now, we come to this conclusion that for each input sequence, outputs produced by both machines are identical. So, these machines are equivalent. In other words, both machines do the same task. But, M_1 has two states and M_2 has four states. So, some states of M_2 are doing the same

task i. e., producing identical outputs on certain input. Such states are known as equivalent states and require extra resources when implemented.
Thus, our goal is to find the simplest and equivalent FSM with minimum number of states.

2.5.1 FSM Minimization

We minimize a FSM using the following method, which finds the equivalent states, and merges these into one state and finally construct the equivalent FSM by minimizing the number of states.

Method : Initially we assume that all pairs (q_0, q_1) over states are non - equivalent states

Step 1 : Construct the transition table.

Step 2 : Repeat for each pair of non - equivalent states (q_0, q_1) :

(a) Do q_0 and q_1 produce same output ?

(b) Do q_0 and q_1 reach the same states for each input $a \in \Sigma$?

(c) If answers of (a) and (b) are YES, then q_0 and q_1 are equivalent states and merge these two states into one state $[q_0, q_1]$ and replace the all occurrences of q_0 and q_1 by $[q_0, q_1]$ and mark these equivalent states.

Step 3 : Check the all - present states, if any redundancy is found, remove that.

Step 4 : Exit.

Example 1 : Consider the following transition table for FSM. Construct minimum state FSM.

	Inputs		
	0	1	
Present State(PS)	Next State (NS)	Next State (NS)	Output
q_0	q_0	q_1	0
q_1	q_2	q_0	1
q_2	q_3	q_0	1
q_3	q_3	q_0	1

After going through this chapter, you should be able to understand :

- Regular sets and Regular Expressions
- Identity Rules
- Constructing FA for a given REs
- Conversion of FA to REs

Unit-II

3.1 REGULAR SETS

A special class of sets of words over S, called regular sets, is defined recursively as follows. (Kleene proves that any set recognized by an FSM is regular. Conversely, every regular set can be recognized by some FSM.)

1. Every finite set of words over S (including ϵ, the empty set) is a regular set.
2. If A and B are regular sets over S, then $A \cup B$ and AB are also regular.
3. If S is a regular set over S, then so is its closure S*.
4. No set is regular unless it is obtained by a finite number of applications of definitions (1) to (3).

i.e., the class of regular sets over S is the smallest class containing all finite sets of words over S and closed under union, concatenation and star operation.

Examples:

i) Let $\Sigma = \{a,b\}$ then the set of strings that contain both odd number of a's and b's is a regular set.

ii) Let $\Sigma = \{0\}$ then the set of strings $\{0,00,000,.....\}$ is a regular set.

iii) Let $\Sigma = \{0,1\}$ then the set of strings $\{01,10\}$ is a regular set.

3.2 REGULAR EXPRESSIONS

The languages accepted by FA are regular languages and these languages are easily described by simple expressions called regular expressions. We have some algebraic notations to represent the regular expressions.

Regular expressions are means to represent certain sets of strings in some algebraic manner and regular expressions describe the language accepted by FA.

If Σ is an alphabet then regular expression(s) over this can be described by following rules.

1. Any symbol from $\Sigma, \in$ *and* ϕ are regular expressions.
2. If r_1 and r_2 are two regular expressions then *union* of these represented as $r_1 \cup r_2$ or $r_1 + r_2$ is also a regular expression
3. If r_1 and r_2 are two regular expressions then *concatenation* of these represented as $r_1 r_2$ is also a regular expression.
4. The Kleene closure of a regular expression r is denoted by r^* is also a regular expression.
5. If r is a regular expression then (r) is also a regular expression.
6. The regular expressions obtained by applying rules 1 to 5 once or more than once are also regular expressions.

Examples :

(1) If $\Sigma = \{a, b\}$, then

(a) a is a regular expression (Using rule 1)
(b) b is a regular expression (Using rule 1)
(c) $a + b$ is a regular expression (Using rule 2)
(d) b^* is a regular expression (Using rule 4)
(e) ab is a regular expression (Using rule 3)
(f) $ab + b^*$ is a regular expression (Using rule 6)

(2) Find regular expression for the following

(a) A language consists of all the words over $\{a, b\}$ ending in b.

(b) A language consists of all the words over $\{a, b\}$ ending in bb.

(c) A language consists of all the words over $\{a, b\}$ starting with a and ending in b.

(d) A language consists of all the words over $\{a, b\}$ having bb as a substring.

(e) A language consists of all the words over $\{a, b\}$ ending in aab.

Solution : Let $\Sigma = \{a, b\}$, and

All the words over $\Sigma = \{\in, a, b, aa, bb, ab, ba, aaa, \ldots\} = \Sigma^*$ *or* $(a + b)^*$ *or* $(a \cup b)^*$

$= (\{\epsilon, a, b, aa, bb, \ldots\})^*$

$= \{\epsilon, a, b, aa, bb, ab, ba, aaa, bbb, abb, baa, aabb, \ldots\}$

= {All the words over $\{a, b\}$}

$\equiv (a + b)^*$

So, $(a^* + b^*)^* \equiv (a + b)^*$

3.3 IDENTITIES FOR REs

The two regular expressions P and Q are equivalent (denoted as P = Q) if and only if P represents the same set of strings as Q does. For showing this equivalence of regular expressions we need to show some identities of regular expressions.

Let P, Q and R are regular expressions then the identity rules are as given below

1. $\epsilon R = R\epsilon = R$
2. $\epsilon^* = \epsilon$ ϵ is null string
3. $(\phi)^* = \epsilon$ ϕ is empty string.
4. $\phi R = R\phi = \phi$
5. $\phi + = R = R$
6. $R + R = R$
7. $RR^* = R^* R = R^+$
8. $(R^*)^* = R^*$
9. $\epsilon + RR^* = R^*$
10. $(P + Q)R = PR + QR$
11. $(P + Q)^* = (P^* Q^*) = (P^* + Q^*)^*$
12. $R^*(\epsilon + R) = (\epsilon + R)R^* = R^*$
13. $(R + \epsilon)^* = R^*$
14. $\epsilon + R^* = R^*$
15. $(PQ)^* P = P(QP)^*$
16. $R^* R + R = R^* R$

3.3.1 Equivalence of two REs

Let us see one important theorem named Arden's Theorem which helps in checking the equivalence of two regular expressions.

Arden's Theorem : Let P and Q be the two regular expressions over the input set Σ. The regular expression R is given as

$$R = Q + RP$$

Which has a unique solution as $R = QP^*$

Proof : Let, P and Q are two regular expressions over the input string Σ.
If P does not contain ϵ then there exists R such that

$$R = Q + RP \qquad \ldots (1)$$

We will replace R by QP* in equation 1.
Consider R. H. S. of equation 1.

$$= Q + QP^*P$$

$$= Q(\epsilon + P^*P)$$

$$= QP^* \qquad \because \epsilon + R^*R = R^*$$

Thus $R = QP^*$

is proved. To prove that $R = QP^*$ is a unique solution, we will now replace L.H.S. of equation 1 by Q + RP. Then it becomes

$$Q + RP$$

But again R can be replaced by Q + RP.

$$\therefore \quad Q + RP = Q + (Q + RP)P$$

$$= Q + QP + RP^2$$

Again replace R by Q + RP.

$$= Q + QP + (Q + RP)P^2$$

$$= Q + QP + QP^2 + RP^3$$

Thus if we go on replacing R by Q + RP then we get,

$$Q + RP = Q + QP + QP^2 + \ldots\ldots + QP^i + RP^{i+1}$$

$$= Q(\epsilon + P + P^2 + \ldots\ldots P^i) + RP^{i+1}$$

From equation 1,

$$R = Q(\epsilon + P + P^2 + \ldots\ldots + P^i) + RP^{i+1} \qquad \ldots (2)$$

Where $i \geq 0$

Consider equation 2,

$$R = Q\underbrace{(\epsilon + P + P^2 + \ldots\ldots + P^i)}_{P^*} + RP^{i+1}$$

$$\therefore \quad R = QP^* + RP^{i+1}$$

Let w be a string of length i.

$= \{\epsilon, 0, 00, 1, 11, 111, 01, 10, \ldots\ldots\}$

= { ϵ, any combination of 0's, any combination of 1's, any combination of 0 and 1 }

Hence, L. H. S. = R. H. S. is proved.

3.4 RELATIONSHIP BETWEEN FA AND RE

There is a close relationship between a finite automata and the regular expression we can show this relation in below figure.

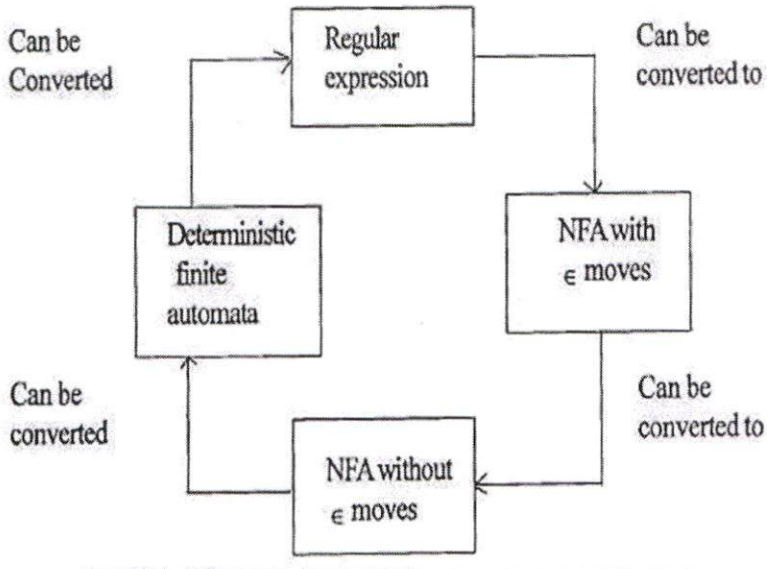

FIGURE : Relationship between FA and regular expression

The above figure shows that it is convenient to convert the regular expression to NFA with ϵ moves. Let us see the theorem based on this conversion.

3.5 CONSTRUCTING FA FOR A GIVEN REs

Theorem : If r be a regular expression then there exists a NFA with ϵ - moves, which accepts $L(r)$.

Proof : First we will discuss the construction of NFA M with ϵ - moves for regular expression r and then we prove that $L(M) = L(r)$.

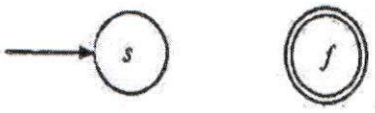
Let r be the regular expression over the alphabet Σ.

Construction of NFA with ϵ - moves

Case 1 :

(i) $r = \phi$

NFA $M = (\{s, f\}, \{\}, \delta, s, \{f\})$ as shown in Figure1 (a)

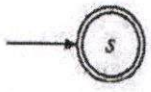


(No path from initial state s to reach the final state f.)

Figure 1 (a)

(ii) $r = \in$

NFA $M = (\{s\}, \{\}, \delta, s, \{s\})$ as shown in Figure 1 (b)

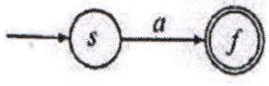


(The initial state s is the final state)

Figure 1 (b)

(iii) $r = a$, for all $a \in \Sigma$,

NFA $M = (\{s, f\}, \Sigma, \delta, s, \{f\})$



(One path is there from initial state s to reach the final state f with label a.)

Figure 1 (c)

Case 2 : $|r| \geq 1$

Let r_1 and r_2 be the two regular expressions over Σ_1, Σ_2 and N_1 and N_2 are two NFA for r_1 and r_2 respectively as shown in Figure 2 (a).

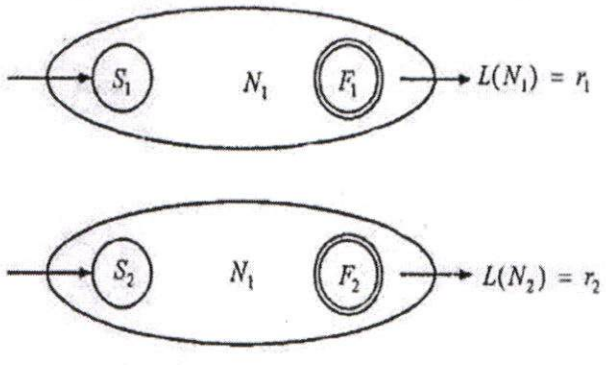


Figure 2 (a) NFA for regular expression r_1 and r_2

Now let us compute for final state, which denotes the regular expression.

r_{12}^3 will be computed, because there are total 2 states and final state is q_1 whose start state is q_0.

$$r_{12}^2 = \left(r_{12}^1\right)\left(r_{22}^1\right)^*\left(r_{22}^1\right) + \left(r_{12}^1\right)$$

$$= 0(\in)^*(\in) + 0$$

$$= 0 + 0$$

$r_{12}^2 = 0$ which is a final regular expression.

3.6.1 Arden's Method for Converting DFA to RE

As we have seen the Arden's theorem is useful for checking the equivalence of two regular expressions, we will also see its use in conversion of DFA to RE.

Following algorithm is used to build the r. e. from given DFA.

1. Let q_0 be the initial state.
2. There are $q_1, q_2, q_3, q_4, \ldots q_n$ number of states. The final state may be some q_j where $j \leq n$.
3. Let α_{ij} represents the transition from q_i *to* q_j.
4. Calculate q_i such that

$$q_i = \alpha_{ij} \cdot q_j$$

   If q_i is a start state

$$q_i = \alpha_{ij} \cdot q_j + \in$$

5. Similarly compute the final state which ultimately gives the regular expression r.

Example 1 : Construct RE for the given DFA.

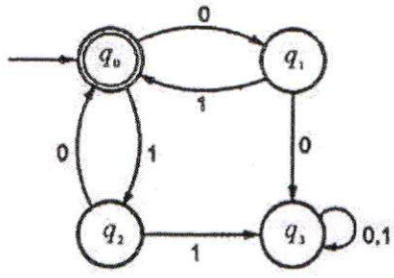
Solution :

Since there is only one state in the finite automata let us solve for q_0 only.

$$q_0 = q_0 0 + q_0 1 + \in$$

$$q_0 = q_0(0+1) + \in$$

Example 3 : Construct RE for the DFA given in below figure.



Solution : Let us see the equations

$$q_0 = q_1 1 + q_2 0 + \epsilon$$
$$q_1 = q_0 0$$
$$q_2 = q_0 1$$
$$q_3 = q_1 0 + q_2 1 + q_3(0+1)$$

Let us solve q_0 first,

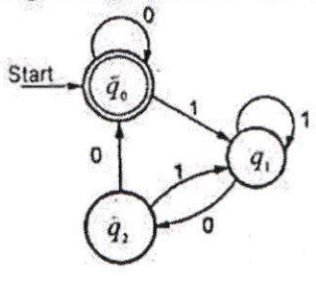
$$q_0 = q_1 1 + q_2 0 + \epsilon$$
$$q_0 = q_0 01 + q_0 10 + \epsilon$$
$$q_0 = q_0(01+10) + \epsilon \qquad \because R = Q + RP$$
$$q_0 = \epsilon(01+10)^* \qquad \Rightarrow QP^* \text{ where}$$
$$q_0 = (01+10)^* \qquad R = q_0, Q = \epsilon, P = (01+10)$$

Thus the regular expression will be

$$r = (01+10)^*$$

Since q_0 is a final state, we are interested in q_0 only.

Example 4 : Find out the regular expression from given DFA.



Example 8 : Show that the language $L = \{a^i\ b^{2i} | i > 0\}$ is not regular.

Solution : The set of strings accepted by language L is,

$L = \{abb, aabbbb, aaabbbbbb, aaaabbbbbbbb...\}$

Applying Pumping lemma for any of the strings above.

Take the string abb.

It is of the form uvw.

Where, $|uv| \leq i, |v| \geq 1$

To find i such that $uv^i w \notin L$

Take i = 2 here, then

$uv^2w = a(bb)b$

$= abbb$

Hence $uv^2w = abbb \notin L$

Since abbb is not present in the strings of L.

$\therefore$ L is not regular.

Example 9 : Show that $L = \{0^n | n$ is a perfect square $\}$ is not regular.

Solution :

Step 1 : Let L is regular by Pumping lemma. Let n be number of states of FA accepting L.

Step 2 : Let $z = 0^n$ then $|z| = n \geq 2$.

Therefore, we can write z = uvw ; Where $|uv| \leq n, |v| \geq 1$.

Take any string of the language L = { 00, 0000, 000000 .... }

Take 0000 as string, here u = 0, v = 0, w = 00 to find i such that $uv^i w \notin L$.

Take i = 2 here, then

$uv^i w = 0(0)^2 00$

$= 00000$

This string 00000 is not present in strings of language L. So $uv^i w \notin L$.

$\therefore$ It is a contradiction.

3.9 PROPERTIES OF REGULAR SETS

Regular sets are closed under following properties.

1. Union
2. Concatenation

3. Kleene Closure
4. Complementation
5. Transpose
6. Intersection

1. Union : If R_1 and R_2 are two regular sets, then union of these denoted by $R_1 + R_2$ or $R_1 \cup R_2$ is also a regular set.

Proof : Let R_1 and R_2 be recognized by NFA N_1 and N_2 respectively as shown in Figure1(a) and Figure1(b).

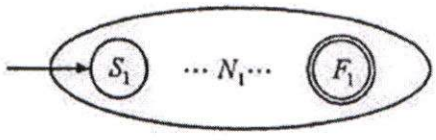


FIGURE 1(a) NFA for regular set R_1

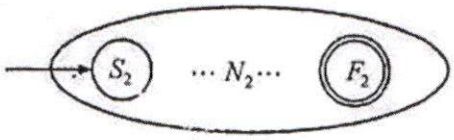

FIGURE 1(b) NFA for regular set R_2

We construct a new NFA N based on union of N_1 and N_2 as shown in Figure 1 (c)

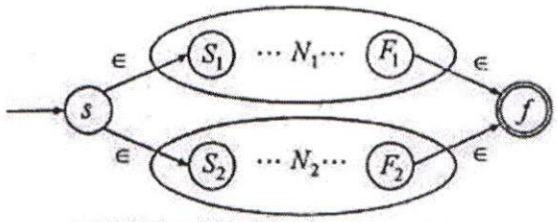

FIGURE 1(c) NFA for $N_1 + N_2$

Now,

$$L(N) = \in L(N_1) \in + \in L(N_2) \in$$
$$= \in R_1 \in + \in R_2 \in$$
$$= R_1 + R_2$$

Since, N is FA, hence $L(N)$ is a regular set (language). Therefore, $R_1 + R_2$ is a regular set.

2. **Concatenation :** If R_1 and R_2 are two regular sets, then concatenation of these denoted by R_1R_2 is also a regular set.

Proof : Let R_1 and R_2 be recognized by NFA N_1 and N_2 respectively as shown in Figure 2(a) and Figure 2(b).

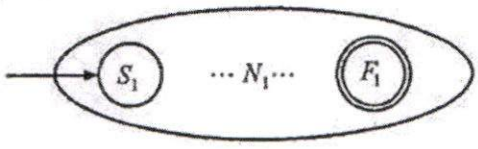

FIGURE 2(a) NFA for regular set R_1

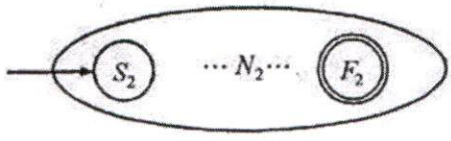

FIGURE 2(b) NFA for regular set R_2

We construct a new NFA N based on concatenation of N_1 and N_2 as shown in Figure2(c).

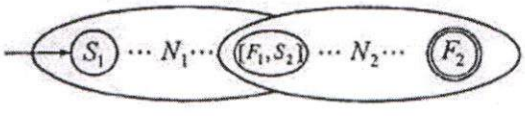

FIGURE 2(c) NFA for regular set R_1R_2

Now,

$L(N)$ = Regular set accepted by N_1 followed by regular set accepted by $N_2 = R_1R_2$

Since, $L(N)$ is a regular set, hence R_1R_2 is also a regular set.

3. **Kleene Closure :** If R is a regular set, then Kleene closure of this denoted by R^* is also a regular set.

Proof : Let R is accepted by NFA N shown in Figure 3(a).

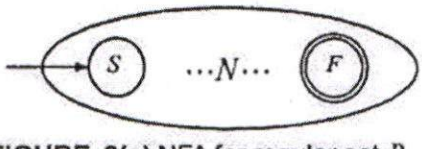

FIGURE 3(a) NFA for regular set R

We construct a new NFA based on NFA N as shown in Figure 3(b).

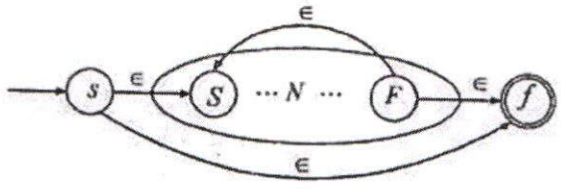

FIGURE 3(b) NFA for regular expression for R^*

Now,

$$L(N) = \{\in, R, R\,R, R\,R\,R, \ldots\}$$

$$= L^*$$

Since, $L(N)$ is a regular set, therefore R^* is a regular set.

4. **Complement :** If R is a regular set on some alphabet Σ, then complement of R is denoted by $\Sigma^* - R$ or $\overline{R}$ is also a regular set.

Proof : Let R be accepted by NFA $N = (Q, \Sigma, \delta, s, F)$. It means, $L(N) = R$. N is shown in Figure 4(a).

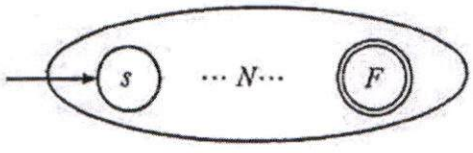

FIGURE 4(a) NFA for regular set R

We construct a new NFA N' based on N as follows :

(a) Change all final states to non-final states.
(b) Change all non-final states to final states.

N' is shown in Figure 4(b)

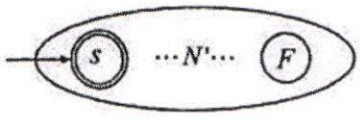

FIGURE 4 (b) NFA

Now,

$L(N')$ = {All the words which are not accepted by NFA N}

= { All the rejected words by NFA N}

$= \Sigma^* - R$

Since, $L(N')$ is a regular set, therefore $(\Sigma^* - R)$ is a regular set.

5. **Transpose :** If R is a regular set, then the transpose denoted by R^T, is also a regular set.

Proof : Let R be accepted by NFA $N = (Q, \Sigma, \delta, s, F)$ as shown in Figure 5(a).

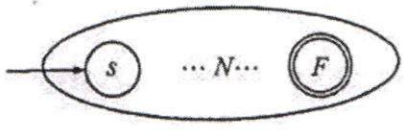

FIGURE 5 (a) NFA N for regular set R

If w is a word in R, then transpose (reverse) is denoted by w^T.

Let $w = a_1 a_2 ... a_n$

Then $w^T = a_n a_{n-1} .... a_1$

We construct a new N' based on N using following rules :

(a) Change the all final states into non-final states and merge all these into one state and make it initial state.

(b) Change initial state to final state.

(c) Reverse the direction of all edges.

N' is shown in Figure5 (b)

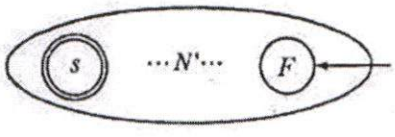

FIGURE 5(b) NFA N' for regular set R^T

Let $w = a_1 a_2 \ldots a_n$ be a word in R, then it is recognized by N and $w^T = a_n a_{n-1} \ldots a_1$ is recognized by N' as shown in Figure5 (b)

In general, we say that if a word w in R is accepted by N, and then N' accepts w^T.

Since, $L(N')$ is a regular set containing all w^T; it means, $L(N') = R^T$.

Thus, R^T is a regular set.

6. **Intersection :** if R_1 and R_2 are two regular sets over Σ, then intersection of these denoted by $R_1 \cap R_2$ is also a regular set.

Proof : By De Morgan's law for two sets A and B over R,

$A \cap B = R^* - ((R^* - A) \cup (R^* - B))$

So, $R_1 \cap R_2 = \Sigma^* - ((\Sigma^* - R_1) \cup (\Sigma^* - R_2))$

Let $R_3 = (\Sigma^* - R_1)$ and $R_4 = (\Sigma^* - R_2)$

So, R_3 and R_4 are regular sets as these are complement of R_1 and R_2.

Let $R_5 = R_3 \cup R_4$

So, R_5 is a regular set because it is the union of two regular sets R_3 and R_4.

Let $R_6 = \Sigma^* - R_5$

So, R_6 is a regular set because it is the complement of regular set R_5.

Therefore, intersection of two regular sets is also regular set.

UNIT-3

REGULAR GRAMMARS

After going through this chapter, you should be able to understand :

- Regular Grammar
- Equivalence between Regular Grammar and FA
- Interconversion

4.1 REGULAR GRAMMAR

Definition : The grammar G = (V, T, P, S) is said to be regular grammar iff the grammar is right linear or left linear.

A grammar G is said to be right linear if all the productions are of the form

$A \rightarrow wB$ and / or $A \rightarrow w$ where $A, B \in V$ and $w \in T^*$.

A grammar G is said to be left linear if all the productions are of the form

$A \rightarrow Bw$ and / or $A \rightarrow w$ where $A, B \in V$ and $w \in T^*$.

Example 1 : The grammar

S → aaB | bbA | ∈
A → aA | b
B → bB | a | ∈

is a right linear grammar. Note that ∈ and string of terminals can appear on RHS of any production and if non - terminal is present on R. H. S of any production, only one non - terminal should be present and it has to be the right most symbol on R. H. S.

Example 2 :

The grammar

S → Baa | Abb | ∈
A → Aa | b
B → Bb | a | ∈

is a left linear grammar. Note that ∈ and string of terminals can appear on RHS of any production and if non - terminal is present on L. H. S of any production, only one non - terminal should be present and it has to be the left most symbol on L. H. S.

Example 3 :

Consider the grammar

$S \rightarrow aA$

$A \rightarrow aB \mid b$

$B \rightarrow Ab \mid a$

In this grammar, each production is either left linear or right linear. But, the grammar is not either left linear or right linear. Such type of grammar is called linear grammar. So, a grammar which has at most one non terminal on the right side of any production without restriction on the position of this non - terminal (note the non - terminal can be leftmost or right most) is called linear grammar.

Note that the language generated from the regular grammar is called regular language. So, there should be some relation between the regular grammar and the FA, since, the language accepted by FA is also regular language. So, we can construct a finite automaton given a regular grammar.

4.2 FA FROM REGULAR GRAMMAR

Theorem : Let G = (V, T, P, S) be a right linear grammar. Then there exists a language L(G) which is accepted by a FA. i. e., the language generated from the regular grammar is regular language.

Proof : Let $V = (q_0, q_1, \ldots)$ be the variables and the start state $S = q_0$ Let the productions in the grammar be

$$q_0 \rightarrow x_1 q_1$$
$$q_1 \rightarrow x_2 q_2$$
$$q_2 \rightarrow x_3 q_3$$
$$\vdots$$
$$q_n \rightarrow x_n q_n$$

Assume that the language L(G) generated from these productions is w. Corresponding to each production in the grammar we can have a equivalent transitions in the FA to accept the string w. After accepting the string w, the FA will be in the final state. The procedure to obtain FA from these productions is given below :

Step 1 : q_0 which is the start symbol in the grammar is the start state of FA.

Step 2 : For each production of the form

$$q_i \rightarrow wq_j$$

the corresponding transition defined will be

$$\delta^*(q_i, w) = q_j;$$

Step 3 : For each production of the form $q_i \rightarrow w$

the corresponding transition defined will be $\delta^*(q_i, w) = q_f$, where q_f is the final state,

As the string $w \in L(G)$ is also accepted by FA, by applying the transitions obtained from step1 through step3, the language is regular. So, the theorem is proved.

Example 1 : Construct a DFA to accept the language generated by the following grammar

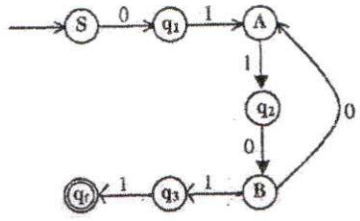
$$S \rightarrow 01A$$
$$A \rightarrow 10B$$
$$B \rightarrow 0A \mid 11$$

Solution :

Note that for each production of the form A → wB, the corresponding transition will be $\delta(A, w) = B$. Also, for each production $A \rightarrow w$, we can introduce the transition $\delta(A, w) = q_f$ where q_f is the final state. The transitions obtained from grammar G is shown using the following table :

Productions			Transitions
S	→	01A	$\delta(S, 01) = A$
A	→	10B	$\delta(A, 10) = B$
B	→	0A	$\delta(B, 0) = A$
B	→	11	$\delta(B, 11) = q_f$

The FA corresponding to the transitions obtained is shown below :



So, the DFA $M = (Q, \Sigma, \delta, q_0, A)$ where

$Q = \{ S, A, B, q_f, q_1, q_2, q_3 \}$, $\Sigma = \{0,1\}$

$q_0 = S$, $A = \{q_f\}$

δ is as obtained from the above table.

The additional vertices introduced are q_1, q_2, q_3.

Example 2 : Construct a DFA to accept the language generated by the following grammar .

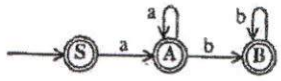
S	→	aA | ∈
A	→	aA| bB | ∈
B	→	bB | ∈

Solution :

Note that for each production of the form $A \to wB$, the corresponding transition will be $\delta(A,w) = B$. Also , for each production $A \to w$, we can introduce the transition $\delta(A,w) = q_f$ where q_f is the final state. The transitions obtained from grammar G is shown using the following table :

Productions			Transitions
S	→	aA	$\delta(S,a) = A$
S	→	∈	S is the final state
A	→	aA	$\delta(A,a) = A$
A	→	bB	$\delta(A,b) = B$
A	→	∈	A is the final state
B	→	bB	$\delta(B,b) = B$
B	→	∈	B is the final state.

Note : For each transition of the form $A \rightarrow \in$, make A as the final state.
The FA corresponding to the transitions obtained is shown below :



So, the DFA $M = (Q, \Sigma, \delta, q_0, A)$ where

$Q = \{S, A, B\}$, $\Sigma = \{a, b\}$

$q_0 = S$, $A = \{S, A, B\}$

δ is as obtained from the above table.

4.3 REGULAR GRAMMAR FROM FA

Theorem : Let $M = (Q, \Sigma, \delta, q_0, A)$ be a finite automaton. If L is the regular language accepted by FA, then there exists a right linear grammar G = (V, T, P, S) so that L = L(G).

Proof : Let $M = (Q, \Sigma, \delta, q_0, A)$ be a finite automata accepting L where

$Q = \{q_0, q_1, \ldots q_n\}$

$\Sigma = \{a_1, a_2, \ldots a_m\}$

A regular grammar G = (V, T, P, S) can be constructed where

$V = \{q_0, q_1, \ldots q_n\}$

$T = \Sigma$

$S = q_0$

The productions P from the transitions can be obtained as shown below :

Step 1 : For each transition of the form $\delta(q_i, a) = q_j$

the corresponding production defined will be $q_i \rightarrow aq_j$

Step 2 : If $q \in A$ i. e., if q is the final state in FA, then introduce the production

$q \rightarrow \in$

As these productions are obtained from the transitions defined for FA, the language accepted by FA is also accepted by the grammar.

UNIT-3

REGULAR GRAMMARS

After going through this chapter, you should be able to understand :

- Regular Grammar
- Equivalence between Regular Grammar and FA
- Interconversion

4.1 REGULAR GRAMMAR

Definition : The grammar G = (V, T, P, S) is said to be regular grammar iff the grammar is right linear or left linear.

A grammar G is said to be right linear if all the productions are of the form

$A \rightarrow wB$ and/or $A \rightarrow w$ where $A, B \in V$ and $w \in T^*$.

A grammar G is said to be left linear if all the productions are of the form

$A \rightarrow Bw$ and/or $A \rightarrow w$ where $A, B \in V$ and $w \in T^*$.

Example 1 : The grammar

$S \rightarrow aaB \mid bbA \mid \in$

$A \rightarrow aA \mid b$

$B \rightarrow bB \mid a \mid \in$

is a right linear grammar. Note that $\in$ and string of terminals can appear on RHS of any production and if non - terminal is present on R. H. S of any production, only one non - terminal should be present and it has to be the right most symbol on R. H. S.

Example 2 :

The grammar

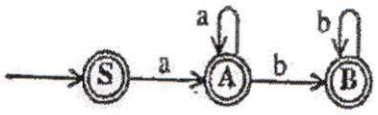
$S \rightarrow Baa \mid Abb \mid \in$

$A \rightarrow Aa \mid b$

$B \rightarrow Bb \mid a \mid \in$

is a left linear grammar. Note that $\in$ and string of terminals can appear on RHS of any production and if non - terminal is present on L. H. S of any production, only one non - terminal should be present and it has to be the left most symbol on L. H. S.

Note : For each transition of the form $A \to \in$, make A as the final state.
The FA corresponding to the transitions obtained is shown below :



So, the DFA $M = (Q, \Sigma, \delta, q_0, A)$ where

$Q = \{S, A, B\}$, $\Sigma = \{a, b\}$

$q_0 = S$, $A = \{S, A, B\}$

δ is as obtained from the above table .

4.3 REGULAR GRAMMAR FROM FA

Theorem : Let $M = (Q, \Sigma, \delta, q_0, A)$ be a finite automaton. If L is the regular language accepted by FA, then there exists a right linear grammar G = (V, T, P, S) so that L = L(G).

Proof : Let $M = (Q, \Sigma, \delta, q_0, A)$ be a finite automata accepting L where

$Q = \{q_0, q_1, \ldots q_n\}$

$\Sigma = \{a_1, a_2, \ldots a_m\}$

A regular grammar G = (V, T, P, S) can be constructed where

$V = \{q_0, q_1, \ldots q_n\}$

$T = \Sigma$

$S = q_0$

The productions P from the transitions can be obtained as shown below :

Step 1 : For each transition of the form $\delta(q_i, a) = q_j$

the corresponding production defined will be $q_i \to aq_j$

Step 2 : If $q \in A$ i. e., if q is the final state in FA, then introduce the production

$q \to \in$

As these productions are obtained from the transitions defined for FA, the language accepted by FA is also accepted by the grammar.

CONTEXT FREE GRAMMARS

After going through this chapter, you should be able to understand :

- Context free grammars
- Left most and Rightmost derivation of strings
- Derivation Trees
- Ambiguity in CFGs
- Minimization of CFGs
- Normal Forms (CNF & GNF)
- Pumping Lemma for CFLs
- Enumeration properties of CFLs

5.1 CONTEXT FREE GRAMMARS

A grammar $G = (V, T, P, S)$ is said to be a CFG if the productions of G are of the form :

$$A \to \alpha, \text{ where } \alpha \in (V \cup T)^*$$

The right hand side of a CFG is not restricted and it may be null or a combination of variables and terminals. The possible length of right hand sentential form ranges from 0 to ∞ i.e., $0 \le |\alpha| \le \infty$.

As we know that a CFG has no context neither left nor right. This is why, it is known as CONTEXT - FREE. *Many programming languages have recursive structure that can be defined by CFG's.*

Example 1 : Consider the grammar $G = (V, T, P, S)$ having productions :
$S \to aSa \mid bSb \mid \in$. Check the productions and find the language generated.

Solution :

Let $P_1 : S \to aSa$ (RHS is terminal variable terminal)

$P_2 : S \to bSb$ (RHS is terminal variable terminal)

$P_3 : S \to \in$ (RHS is null string)

Since, all productions are of the form $A \to \alpha$, where $\alpha \in (V \cup T)^*$, hence G is a CFG.

So, the final grammar to generate the language $L = \{ w \mid n_a(w) = n_b(w) \}$ is G = (V, T, P, S) where

V = { S } , T = { a, b }

P = { $S \to \in$

$S \to aSb$

$S \to bSa$

$S \to SS$

} S is the start symbol

5 . 2 LEFTMOST AND RIGHTMOST DERIVATIONS

Leftmost derivation :

If $G = (V, T, P, S)$ is a CFG and $w \in L(G)$ then a derivation $S \underset{L}{\overset{*}{\Rightarrow}} w$ is called leftmost derivation if and only if all steps involved in derivation have leftmost variable replacement only.

Rightmost derivation :

If $G = (V, T, P, S)$ is a CFG and $w \in L(G)$, then a derivation $S \underset{R}{\overset{*}{\Rightarrow}} w$ is called rightmost derivation if and only if all steps involved in derivation have rightmost variable replacement only.

Example 1 : Consider the grammar $S \to S + S \mid S * S \mid a \mid b$. Find leftmost and rightmost derivations for string $w = a * a + b$.

Solution :

Leftmost derivation for $w = a * a + b$

$S \underset{L}{\Rightarrow} S * S$ (Using $S \to S * S$)

$\underset{L}{\Rightarrow} a * S$ (The first left hand symbol is a, so using $S \to a$)

$\underset{L}{\Rightarrow} a * S + S$ (Using $S \to S + S$, in order to get $a + b$)

$\underset{L}{\Rightarrow} a * a + S$ (Second symbol from the left is a, so using $S \to a$)

$\underset{L}{\Rightarrow} a * a + b$ (The last symbol from the left is b, so using $S \to b$)

Rightmost derivation for $w = a * a + b$

$S \underset{R}{\Rightarrow} S * S$ (Using $S \rightarrow S * S$)

$\underset{R}{\Rightarrow} S * S + S$ (Since, in the above sentential form second symbol from the right is * so, we can not use $S \rightarrow a|b$. Therefore, we use $S \rightarrow S + S$)

$\underset{R}{\Rightarrow} S * S + b$ (Using $S \rightarrow b$)

$\underset{R}{\Rightarrow} S * a + b$ (Using $S \rightarrow a$)

$\underset{R}{\Rightarrow} a * a + b$ (Using $S \rightarrow a$)

Example 2 : Consider a CFG $S \rightarrow bA|aB$, $A \rightarrow aS|aAA|a$, $B \rightarrow bS|aBB|b$. Find leftmost and rightmost derivations for $w = aaabbabbba$.

Solution :

Leftmost derivation for $w = aaabbabbba$:

$S \Rightarrow aB$ (Using $S \rightarrow aB$ to generate first symbol of w)

$\Rightarrow aaBB$ (Since, second symbol is a, so we use $B \rightarrow aBB$)

$\Rightarrow aaaBBB$ (Since, third symbol is a, so we use $B \rightarrow aBB$)

$\Rightarrow aaabBB$ (Since fourth symbol is b, so we use $B \rightarrow b$)

$\Rightarrow aaabbB$ (Since, fifth symbol is b, so we use $B \rightarrow b$)

$\Rightarrow aaabbaBB$ (Since, sixth symbol is a, so we use $B \rightarrow aBB$)

$\Rightarrow aaabbabB$ (Since, seventh symbol is b, so we use $B \rightarrow b$)

$\Rightarrow aaabbabbS$ (Since, eighth symbol is b, so we use $B \rightarrow bS$)

$\Rightarrow aaabbabbbA$ (Since, ninth symbol is b, so we use $S \rightarrow bA$)

$\Rightarrow aaabbabbba$ (Since, the tenth symbol is a, so using $A \rightarrow a$)

Rightmost derivation for $w = aaabbabbba$

$S \Rightarrow aB$ (Using $S \rightarrow aB$ to generate first symbol of w)

$\Rightarrow aaBB$ (We need a as the rightmost symbol and second symbol from the left side, so we use $B \rightarrow aBB$)

$\Rightarrow aaBbS$ (We need a as rightmost symbol and this is obtained from A only, we use $B \rightarrow bS$)

$\Rightarrow aaBbbA$ (Using $S \rightarrow bA$)

$\Rightarrow aaBbba$ (Using $A \rightarrow a$)

$\Rightarrow aaaBBbba$ (We need b as the fourth symbol from the right)

$\Rightarrow aaaBbbba$ (Using $B \rightarrow b$)

$\Rightarrow aaabSbbba$ (Using $B \rightarrow bS$)

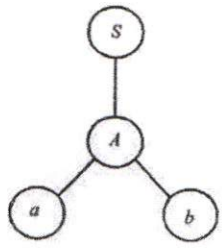


Figure (c) Parse tree for $w = ab$

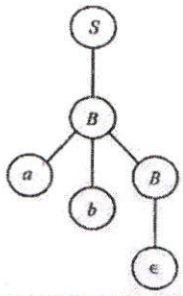

Figure (d) Parse tree for $w = ab$

So, the given grammar is ambiguous.

5.4.1 Removal of Ambiguity

5.4.1.1 Left Recursion

A grammar can be changed from one form to another accepting the same language. If a grammar has left recursive property, it is undesirable and left recursion should be eliminated. The left recursion is defined as follows.

Definition : A grammar G is said to be left recursive if there is some non terminal A such that $A \Rightarrow^{+} A\alpha$. In other words, in the derivation process starting from any non - terminal A, if a sentential form starts with the same non - terminal A, then we say that the grammar is having left recursion.

Elimination of Left Recursion

The left recursion in a grammar G can be eliminated as shown below. Consider the A - production of the form $A \to A\alpha_1 | A\alpha_2 | A\alpha_3 ..... A\alpha_n | \beta_1 | \beta_2 | \beta_3 ..... \beta_m$

where β_i's do not start with A. Then the A productions can be replaced by

$$A \to \beta_1 A^1 | \beta_2 A^1 | \beta_3 A^1 | ..... \beta_m A^1$$

$$A^1 \to \alpha_1 A^1 | \alpha_2 A^1 | \alpha_3 A^1 | ..... | \alpha_n A^1 | \epsilon$$

Note that α_i's do not start with A^1.

Example 1 : Eliminate left recursion from the following grammar

$$E \to E+T | T$$

$$T \to T * F | F$$

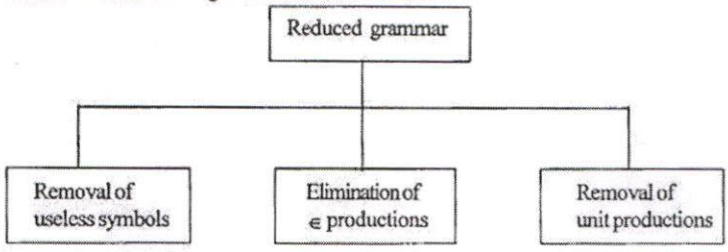
$$F \to (E) | id$$

5.5 MINIMIZATION OF CFGs

As we have seen various languages can effectively be represented by context free grammar. All the grammars are not always optimized. That means grammar may consists of some extra symbols (non - terminals). Having extra symbols unnecessary increases the length of grammar. Simplification of grammar means reduction of grammar by removing useless symbols. The properties of reduced grammar are given below :

1. Each variable (i. e. non - terminal) and each terminal of G appears in the derivation of some word in L.
2. There should not be any production as $X \to Y$ where X and Y are non - terminals.
3. If $\in$ is not in the language L then there need not be the production $X \to \in$.

We see the reduction of grammar as shown below :



5.5.1 Removal of useless symbols

Definition : A symbol X is useful if there is a derivation of the form

$$S \Rightarrow^* \alpha X \beta \Rightarrow^* w$$

Otherwise, the symbol X is useless. Note that in a derivation, finally we should get string of terminals and all these symbols must be reachable from the start symbol S. Those symbols and productions which are not at all used in the derivation are useless.

Theorem 5.5.1 : Let G = (V, T, P, S) be a CFG. We can find an equivalent grammar $G_1 = (V_1, T_1, P_1, S)$ such that for each A in $(V_1 \cup T_1)$ there exists α and β in $(V_1 \cup T_1)^*$ and x in T^+ for which $S \Rightarrow^* \alpha A \beta \Rightarrow^* x$.

P_1	T_1	V_1
-	-	S
S → a | Bb | Aa	a, b	S, A, B
A → a B	a, b	S, A, B
B → a | A a	a, b	S, A, B

The resulting grammar $G_1 = (V_1, T_1, P_1, S)$ where

V_1 = { S, A, B }

T_1 = { a, b }

P_1 = {

S → a | Bb | aA
A → aB
B → a | Aa

} S is the start symbol

such that each symbol X in $(V_1 \cup T_1)$ has a derivation of the form $S \Rightarrow^* \alpha X \beta \Rightarrow^* w$.

5.5.2 Eliminating ϵ - productions

A production of the form $A \rightarrow \epsilon$ is undesirable in a CFG, unless an empty string is derived from the start symbol. Suppose, the language generated from a grammar G does not derive any empty string and the grammar consists of ϵ - productions. Such ϵ - productions can be removed. An ϵ - production is defined as follows :

Definition 1 : Let G = (V, T, P, S) be a CFG. A production in P of the form

$$A \rightarrow \epsilon$$

is called an ϵ - production or NULL production. After applying the production the variable A is erased. For each A in V, if there is a derivation of the form

$$A \Rightarrow^* \epsilon$$

then A is a nullable variable.

Example : Consider the grammar

S → ABCa | bD
A → BC | b
B → b | ϵ

Step 2 : Construction of productions P_1. Add a non ϵ- production in P to P_1. Take all the combinations of nullable variables in a production, delete subset of nullable variables one by one and add the resulting productions to P_1.

Productions	Resulting productions (P_1)
S → BAAB	S → BAAB | AAB | BAB | BAA | AB | BB | BA | AA | A | B
A → 0A 2	A → 0A2 | 02
A → 2A0	A → 2A0 | 20
B → AB	B → AB | B | A
B → 1 B	B → 1 B | 1

We can delete the productions of the form A → A. In P_1, the production $B \rightarrow B$ can be deleted and the final grammar obtained after eliminating ϵ -productions is shown below.

The grammar $G_1 = (V_1, T_1, P_1, S)$ where

V_1 = { S, A, B, C, D }

T_1 = { a, b, c, d }

P_1 = { S → BAAB \| AAB \| BAB \| BAA \| AB \| BB \| BA \| AA \| A \| B
A → 0A2 \| 02 \| 2A0 \| 20
B → AB \| A \| 1B \| 1
} S is the start symbol

5.5.3 Eliminating unit productions

Consider the production $A \rightarrow B$. The left hand side of the production and right hand side of the production contains only one variable. Such productions are called unit productions. Formally, a unit production is defined as follows.

Definition : Let G = (V, T, P, S) be a CFG. Any production in G of the form

$$A \rightarrow B$$

where A, $B \in V$ is a unit production.
In any grammar, the unit productions are undesirable. This is because one variable is simply replaced by another variable.

In a CFG, there is no restriction on the right hand side of a production. The restrictions are imposed on the right hand side of productions in a CFG resulting in normal forms. The different normal forms are :

1. Chomsky Normal Form (CNF)
2. Greiback Normal Form (GNF)

5.6.1 Chomsky Normal Form (CNF)

Chomsky normal form can be defined as follows.

Non - terminal → Non - terminal.Non - terminal
Non - terminal → terminal

The given CFG should be converted in the above format then we can say that the grammar is in CNF. Before converting the grammar into CNF it should be in reduced form. That means remove all the useless symbols, ϵ productions and unit productions from it. Thus this reduced grammar can be then converted to CNF.

Definition :
Let G = (V, T, P, S) be a CFG. The grammar G is said to be in CNF if all productions are of the form

$$\begin{array}{lcl} A & \rightarrow & BC \\ & \text{or} & \\ A & \rightarrow & a \end{array}$$

where A, B and $C \in V$ and $a \in T$.

Note that if a grammar is in CNF, the right hand side of the production should contain two symbols or one symbol. If there are two symbols on the right hand side those two symbols must be non - terminals and if there is only one symbol, that symbol must be a terminal.

Theorem 5.6.1 : Let G = (V, T, P, S) be a CFG which generates context free language without ϵ. We can find an equivalent context free grammar $G_1 = (V_1, T, P_1, S)$ in CNF such that $L(G) = L(G_1)$ i. e., all productions in G_1 are of the form

$$\begin{array}{lcl} A & \rightarrow & BC \\ & \text{or} & \\ A & \rightarrow & a \end{array}$$

Thus, from (7), (8) and (9), the resultant grammar becomes :

$$S \rightarrow V_1 S \mid V_2 V_5 V_6 \mid a \mid b$$
$$V_1 \rightarrow -$$
$$V_2 \rightarrow [$$
$$V_5 \rightarrow SV_3 \qquad \text{.....(C)}$$
$$V_6 \rightarrow SV_4$$
$$V_3 \rightarrow \uparrow$$
$$V_4 \rightarrow]$$

Now, in the resultant grammar (C), following is the production which is not in the form of CNF:

$$S \rightarrow V_2 V_5 V_6$$

We can write this production as :

$$S \rightarrow V_2 V_7 \qquad \text{.....(10)}$$
$$V_7 \rightarrow V_5 V_6 \qquad \text{.....(11)}$$

Thus, from (10) and (11), the resultant grammar becomes :

$$S \rightarrow V_1 S \mid V_2 V_7 \mid a \mid b$$
$$V_1 \rightarrow -$$
$$V_2 \rightarrow [$$
$$V_7 \rightarrow V_5 V_6 \qquad \text{.....(D)}$$
$$V_5 \rightarrow SV_3$$
$$V_6 \rightarrow SV_4$$
$$V_3 \rightarrow \uparrow$$
$$V_4 \rightarrow]$$

Thus, the resultant grammar (D) is in the form of CNF, which is the required solution.

5.6.2 Greibach Normal form (GNF)

Greibach normal form can be defined as follows :

Non - terminal → one terminal. Any number of non - terminals

Example :

$S \rightarrow aA$ is in GNF
$S \rightarrow a$ is in GNF

From the subtree shown in figure (b), we get $S \overset{*}{\Rightarrow} aaS\epsilon$ or $S \overset{*}{\Rightarrow} z_3 S z_4$ and considering the subtree shown in figure(c), we get $S \overset{*}{\Rightarrow} a$ or $S \overset{*}{\Rightarrow} z_2$.

The subtree shown in figure (b) can be added as many times as we like in the parse tree shown in figure (a). So, $S \overset{*}{\Rightarrow} z_3^i S z_4^i \overset{*}{\Rightarrow} z_3^i z_2 z_4^i$

Therefore, string z can be written as $uz_3z_2z_4y$ for some u and y substrings of z. The substrings z_3 and z_4 can be pumped as many times as we like. Replacing z_3, z_2 and z_4 by v, w and x respectively, we get z = uvwxy and $S \overset{*}{\Rightarrow} uv^iwx^iy$ for some i = 0, 1, 2, ...
Hence, the statement of theorem is proved.

Application of Pumping Lemma for CFLs

We use the pumping lemma to prove certain languages are not CFL. We proceed as we have seen in application of pumping lemma for regular sets and get contradiction. The result of this lemma is always negative.

Procedure for Proving Language is not Context - free

The following steps are considered to show a given language is not context - free.

Step 1 :

Suppose that L is context - free. Let l be the natural number obtained by using pumping lemma.

Step 2 :

Choose a string $x \in L$ such that $|x| \geq l$ using pumping lemma principle write z = uvwxy.

Step 3 :

Find suitable i so that $uv^iwx^iy \notin L$. This is a contradiction. So L is not context - free.

Case 2 :

$v \in a^+$ and $x \in c^*$. Let $v = a^p$ and pq=n!. Pumping v and x, $(q+1)$ times, we get : $z' = uv^{q+1}wx^{q+1}y$.

In z', no. of a's will be $n - p + n! + p = n! + n$.

No.of b's in z' will remain n! + n. Hence, no. of a's = no. of b's in z'.

Similarly, in other cases, we can arrive at strings not as per specification of L.

Hence, L is not context free.

5.8 CLOSURE PROPERTIES OF CFLs

The closure properties that hold for regular languages do not always hold for context free languages. Consider those operations which preserve CFL.

The purpose of these operations are to prove certain languages are CFL and certain languages are not CFL.

Context-free languages are closed under following properties.

1. Union
2. Concatenation and
3. Kleene Closure (Context-free languages **may** or **may not** close under following properties)
4. Intersection
5. Complementation

Theorem 5.8.1 : If L_1 and L_2 are two CFLs, then union of L_1 and L_2 denoted by $L_1 + L_2$ or $L_1 \cup L_2$ is also a CFL.

Proof :

Let CFG $G_1 = (V_1, T_1, P, S)$ generates L_1 and CFG $G_2 = (V_2, T_2, P, S)$ generates L_2 and $G = (V, T, P, S)$ generates $L = L_1 + L_2$.

We construct G as follows :

Step 1 : Rename the variables of CFG G_1

If $V_1 = \{S, A, B, ..., X\}$, then the renamed variables are $\{S_1, A_1, B_1, ...X_1\}$. This modification should be reflected in productions also.

Step 2 : Rename the variables of CFG G_2

If $V_2 = \{S, A, B, \ldots X\}$, then the renamed variables are $\{S_2, A_2, B_2 \ldots . X_2\}$. This modification should be reflected in production also.

Step 3 : We get of the productions of G_1 and G_2 to get productions of G as follows :

$S \rightarrow S_1 \mid S_2$, where S_1 and S_2 are starting symbols of grammars G_1 and G_2 respectively and S_1 - productions and S_2 - productions remain unchanged.

$T = T_1 \cup T_2$,

$V = \{S_1, A_1, B_1, \ldots X_1\} \cup \{S_2, A_2, B_2, \ldots X_2\}$

Since, all productions of G_1 and G_2 including $S \rightarrow S_1 \mid S_2$ are in context-free form, so G is a CFG.

Language generated by G :

$L(G)$ = Language generated from (S_1 *or* S_2)

= Language generated from S_1 or language generated from S_2

= $L(G_1)$ or $L(G_2)$ (Since, S_1 and S_2 are starting symbols of G_1 and G_2 respectively.)

= L_1 *or* L_2 (Since, G_1 produces L_1 and G_2 produces L_2.)

= $L_1 + L_2$

Hence, statement of the theorem is proved.

Example : Consider the CFGs $S \rightarrow aSb \mid ab$ and $S \rightarrow cSdd \mid cdd$, which generate languages L_1 and L_2 respectively. Construct grammar for $L = L_1 + L_2$.

Solution :

Let G_1 generates L_1 and G_2 generates L_2 and $G = (V, T, P, S)$ generates $L = L_1 + L_2$.

Renaming the variables of G_1 and G_2, we get

$V_1 = \{S_1\}$ and $V_2 = \{S_2\}$, where S_1 - productions are $S_1 \rightarrow aS_1b \mid ab$, and S_2 - productions are $S_2 \rightarrow cS_2dd \mid cdd$

UNIT-4

PUSH DOWN AUTOMATA

After going through this chapter, you should be able to understand :

- Push down automata
- Acceptance by final state and by empty stack
- Equivalence of CFL and PDA
- Interconversion
- Introduction to DCFL and DPDA

6.1 INTRODUCTION

A PDA is an enhancement of finite automata (FA). Finite automata with a stack memory can be viewed as pushdown automata. Addition of stack memory enhances the capability of Pushdown automata as compared to finite automata. The stack memory is potentially infinite and it is a data structure. Its operation is based on last - in - first - out (LIFO). It means, the last object pushed on the stack is popped first for operation. We assume a stack is long enough and linearly arranged. We add or remove objects at the left end.

6.1.1 Model of Pushdown Automata (PDA)

A model of pushdown automata is shown in below figure. It consists of a finite tape, a reading head, which reads from the tape, a stack memory operating in LIFO fashion.

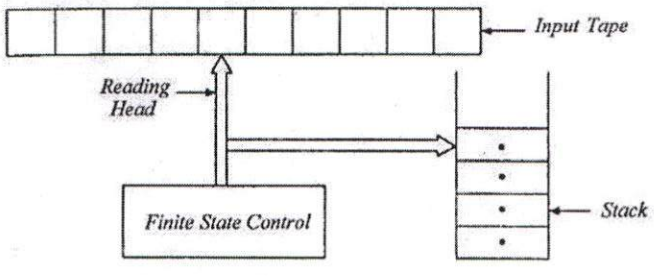


FIGURE : Model of Pushdown Automata

There are two alphabets ; one for input tape and another for stack. The stack alphabet is denoted by Γ and input alphabet is denoted by Σ. PDA reads from both the alphabets ; one symbol from the input and one symbol from the stack.

6.1.2 Mathematical Description of PDA

A pushdown automata is described by 7 - tuple $(Q,\Sigma,\Gamma,\delta,q_0,Z_0,F)$, where

1. Q is finite and nonempty set of states,
2. Σ is input alphabet,
3. Γ is finite and nonempty set of pushdown symbols,
4. δ is the transition function which maps
   From $Q \times (\Sigma \cup \{\in\}) \times \Gamma$ to (**finite subset** of) $Q \times \Gamma^*$,
5. $q_0 \in Q$, is the starting state,
6. $Z_0 \in \Gamma$, is the starting (top most or initial) stack symbol, and
7. $F \subseteq Q$, is the set of final states.

6.1.3 Moves of PDA

The move of PDA means that what are the options to proceed further after reading inputs in some state and writing some string on the stack. As we have discussed earlier that PDA is nondeterministic device having some finite number of choices of moves in each situation.

The **move** will be of two types :

1. In the first type of move, an input symbol is read from the tape, it means, the head is advanced and depending upon the topmost symbol on the stack and present state, PDA has number of choices to proceed further.
2. In the second type of move, the input symbol is not read from the tape, it means, head is not advanced and the topmost symbol of stack is used. The topmost of stack is modified without reading the input symbol. It is also known as an $\in$ - move.

Mathematically first type of move is defined as follows.

$\delta(q,a,Z) = \{(p_1,\alpha_1),(p_2,\alpha_2),\ldots(p_n,\alpha_n)\}$, where for $1 \le i \le n$, q, p_i are states in Q, $a \in \Sigma$, $Z \in \Gamma$, *and* $\alpha_i \in \Gamma^*$.

PDA reads an input symbol a and one stack symbol Z in present state q and for any value(s) of i, enters state p_i, replaces stack symbol Z by string $\alpha_i \in \Gamma^*$, and head is advanced one cell on the tape. Now, the leftmost symbol of string α_i is assumed as the topmost symbol on the stack.

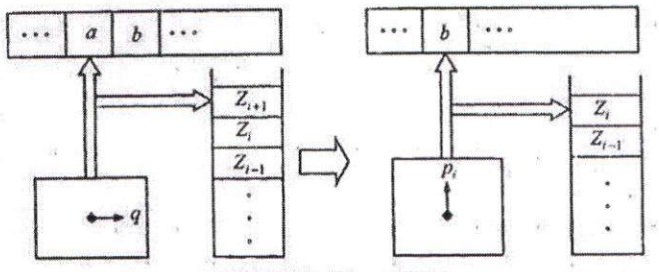
Mathematically second type of move is defined as follows.

$\delta(q,\in,Z) = \{(p_1,\alpha_1),(p_2,\alpha_2),\ldots(p_n,\alpha_n)\}$, where for $1 \le i \le n$, q, p_i are states in Q, $a \in \Sigma$, $Z \in \Gamma$, *and* $\alpha_i \in \Gamma^*$.

PDA does not read input symbol but it reads stack symbol Z in present state q and for any value(s) of i, enters state p_i, replaces stack symbol Z by string $\alpha_i \in \Gamma^*$, and head is not advanced on the tape. Now, the leftmost symbol of string α_i is assumed as the topmost symbol on the stack.

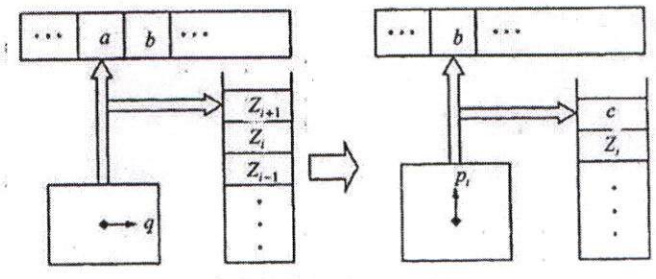
The **string** α_i be any one of the following :

1. $\alpha_i = \in$ in this case the topmost stack symbol Z_{i+1} is erased and second topmost symbol becomes the topmost symbol in the next move. It is shown in figure (a).



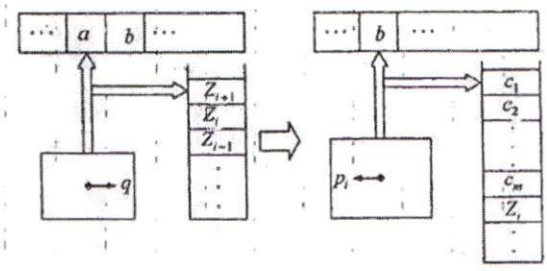
FIGURE(a): Move of PDA

2. $\alpha_i = c, c \in \Gamma$, in this case the topmost stack symbol Z_{i+1} is replaced by symbol c. It is shown in figure(b)



FIGURE(b): Move of PDA

3. $\alpha_i = c_1 c_2 \ldots c_m$, in this case the topmost stack symbol Z_{i+1} is replaced by string $c_1 c_2 \ldots c_m$. It is shown in figure(c).



FIGURE(c): Move of PDA

6.1.4 Instantaneous Description (ID) of PDA

Let PDA $M = (Q,\Sigma,\Gamma,\delta,q_0,Z_0,F)$, then its configuration at a given instant can be defined by instantaneous description (ID). An ID includes state, remaining input string, and remaining stack string (symbols). So, an ID is (q,x,α), where $q \in Q, x \in \Sigma^*, \alpha \in \Gamma^*$.

The relation between two consecutive IDs is represented by the sign $\vdash$.

We say $(q,ax,Z\beta) \vdash_M (p,x,\alpha\beta)$ if $\delta(q,a,Z)$ contains (p,α), where $Z,\beta,\alpha \in \Gamma^*$, a may be null or $a \in \Sigma$, $p,q \in Q$ for M

The reflexive and transitive closure of the relation $\vdash_M$ is denoted by $\vdash_M^*$

Properties :

1. If $(q,x,\alpha) \vdash_M^* (p,\in,\alpha)$, where $\alpha \in \Gamma^*, x \in \Sigma^*$, and $p,q \in Q$, then for all $y \in \Sigma^*$. $(q,xy,\alpha) \vdash_M^* (p,y,\alpha)$,
2. If $(q,xy,\alpha) \vdash_M^* (p,y,\alpha)$, where $\alpha \in \Gamma^*, x,y \in \Sigma^*$, and $p,q \in Q$, then $(q,x,\alpha) \vdash_M^* (p,\in,\alpha)$, and
3. If $(q,x,\alpha) \vdash_M^* (p,\in,\beta)$, where $\alpha,\beta \in \Gamma^*, x \in \Sigma^*$, and $p,q \in Q$, then $(q,x,\alpha\,\gamma) \vdash_M^* (p,\in,\beta\gamma)$, where $\gamma \in \Gamma^*$

6.1.5 Acceptance by PDA

Let M be a PDA, the accepted language is represented by N(M). We defined the acceptance by PDA in two ways.

1. Let $M = (Q,\Sigma,\Gamma,\delta, q_0, Z_0,F)$, then N(M) is accepted by final state such that

   $N(M)=\{w:(q_0,w,Z_0)\vdash_M^*(q_f,\in,\beta)$, where $q \in Q$, $w \in \Sigma^*, Z_0, \beta \in \Gamma^*$, and $q_f \in F\}$

   It is similar to the acceptance by FA discussed earlier. We define some final states and the accepted language *N(M)* is the set of all input strings for which some choice of moves leads to some final state.

2. Let $M = (Q,\Sigma,\Gamma,\delta,q_0,Z_0,\phi)$, then *N(M)* is accepted by empty stack or null stack such that $N(M) = \{w:(q_0,w,Z_0)\vdash_M^*(p,\in,\in)$, where $p \in Q, w \in \Sigma^*\}$

   The language *N(M)* is the set of all input strings for which some sequence of moves causes the PDA to empty its stack.

Note : If acceptance is defined by empty stack then there is no meaning of final state and it is represented by ϕ.

Example : consider a PDA $M = (\{q_0,q_1,q_2\},\{a,c\},\{a,Z_0\},\delta,q_0,Z_0,\{q_2\})$ shown in below figure. Check the acceptability of string aacaa.

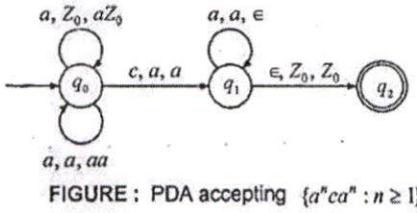


FIGURE : PDA accepting $\{a^n ca^n : n \geq 1\}$

Note : *Edges are labeled with Input symbol, stack symbol, written symbol on the stack.*

Solution :

The transition function δ is defined as follows :

$\delta(q_0,a,Z_0) = \{(q_0,aZ_0)\}$,

$\delta(q_0,a,a) = \{(q_0,aa)\}$,

$\delta(q_0,c,a) = \{(q_1,a)\}$,

$\delta(q_1,a,a) = \{(q_1,\in)\}$, and

$\delta(q_1,\in,Z_0) = \{(q_2,Z_0)\}$

Following moves are carried out in order to check acceptability of string $aacaa$:

$$(q_0,aacaa,Z_0) \vdash (q_0,acaa,aZ_0)$$
$$\vdash (q_0,caa,aaZ_0)$$
$$\vdash (q_1,aa,aaZ_0)$$
$$\vdash (q_1,a,aZ_0)$$
$$\vdash (q_1,\in,Z_0)$$
$$\vdash (q_2,\in,Z_0)$$

Hence, $(q_0,aacaa,Z_0) \overset{*}{\vdash}_M (q_2,\in,Z_0)$.

Therefore, the string **aacaa** is accepted by M.

6. 2 CONSTRUCTION OF PDA

In this section, we shall see how PDA's can be constructed.

Example 1 : Obtain a PDA to accept the language $L(M) = \{ wCw^R \mid w \in (a+b)^* \}$ where w^R is reverse of W .

Solution:

It is clear from the language $L(M) = \{ wCw^R \}$ that if $w = abb$

then reverse of w denoted by w^R will be $w^R = bba$ and the language L will be wCw^R
i. e., abbCbba which is a string of palindrome.

To accept the string :

The sequence of moves made by the PDA for the string **aabCbaa** is shown below.

Initial ID

$(q_0, aabCbaa, Z_0) \vdash (q_0, abCbaa, aZ_0)$

$\vdash (q_0, bCbaa, aaZ_0)$

$\vdash (q_0, Cbaa, baaZ_0)$

$\vdash (q_1, baa, baaZ_0)$

$\vdash (q_1, aa, aaZ_0)$

$\vdash (q_1, a, aZ_0)$

$\vdash (q_1, \in, Z_0)$

$\vdash (q_2, \in, Z_0)$

(Final Configuration)

Since q_2 is the final state and input string is $\in$ in the final configuration, the string **aabCbaa** is accepted by the PDA.

To reject the string :

The sequence of moves made by the PDA for the string **aabCbab** is shown below.

Initial ID

$(q_0, aabCbab, Z_0) \vdash (q_0, abCbab, aZ_0)$

$\vdash (q_0, bCbab, aaZ_0)$

$\vdash (q_0, Cbab, baaZ_0)$

$\vdash (q_1, bab, baaZ_0)$

$\vdash (q_1, ab, aaZ_0)$

$\vdash (q_1, b, aZ_0)$

(Final Configuration)

Since the transition $\delta(q_1, b, a)$ is not defined, the string **aabCbab** is not a palindrome and the machine halts and the string is rejected by the PDA.

Example 2 : Obtain a PDA to accept the language $L = \{ a^n b^n \mid n \geq 1 \}$ by a final state.

Solution :

The machine should accept n number of a's followed by n number of b's.

6.3 DETERMINISTIC AND NONDETERMINISTIC PUSHDOWN AUTOMATA

In this section, we will discuss about the deterministic and nondeterministic behavior of pushdown automata.

6.3.1 Nondeterministic PDA (NPDA)

Like NFA, nondeterministic PDA (NPDA) has finite number of choices for its inputs. As we have discussed in the mathematical description that transition function δ which maps from $Q \times (\Sigma \cup \{\epsilon\}) \times \Gamma$ to (**finite subset** of) $Q \times \Gamma^*$. A nondeterministic PDA accepts an input if a sequence of choices leads to some final state or causes PDA to empty its stack. Since, sometimes it has more than one choice to move further on a particular input ; it means, PDA guesses the right choice always, otherwise it will fail and will be in hang state.

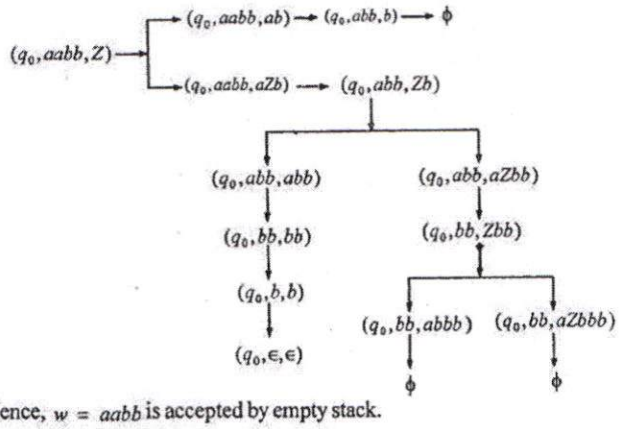
Example : consider a nondeterministic PDA $M = (\{q_0\},\{a,b\},\{a,b,Z\},\delta,q_0,Z,\phi)$, for the language $L = \{a^n b^n : n \geq 1\}$, where δ is defined as follows :

$\delta(q_0,\epsilon,Z) = \{(q_0,ab),(q_0,aZb)\}$ (Two possible moves for input ϵ on the tape and Z on the stack),

$\delta(q_0,a,a) = \{(q_0,\epsilon)\}$, and $\delta(q_0,b,b) = \{(q_0,\epsilon)\}$

Check whether string $w = aabb$ is accepted or not ?

Solution : Initial configuration is $(q_0,aabb,Z)$. Following moves are possible :



Hence, $w = aabb$ is accepted by empty stack.

One thing is noticeable here that only one move sequence leads to empty store and other don't. In other words, we say that some move sequence(s) leads to accepting configuration and other lead to hang state.

6.3.2 Deterministic PDA (DPDA)

Deterministic PDA (DPDA) is just like DFA, which has *at most one choice* to move for certain input. A PDA $M = (Q, \Sigma, \Gamma, \delta, q_0, Z_0, F)$ is deterministic if it satisfies both the conditions given as follows :

1. For any $q \in Q$, $a \in (\Sigma \cup \{\in\})$, and $Z \in \Gamma$, $\delta(q, a, Z)$ has at most one choice of move.
2. For any $q \in Q$, and $Z \in \Gamma$, if $\delta(q, \in, Z)$ is defined i.e. $\delta(q, \in, Z) \neq \phi$, then $\delta(q, a, Z) = \phi$ for all $a \in \Sigma$

Example : Consider a DPDA $M = (\{q_0, q_1\}, \{a,c\}, \{a, Z_0\}, \delta, q_0, Z_0, \phi)$ accepting the language $\{a^n c a^n : n \geq 1\}$, where δ is defined as follows :

$\delta(q_0, a, Z_0) = \{(q_0, aZ_0)\}$

$\delta(q_0, a, a) = \{(q_0, aa)\}$,

$\delta(q_0, c, a) = \{(q_1, a)\}$,

$\delta(q_1, a, a) = \{(q_1, \in)\}$, and $\delta(q_1, \in, Z_0) = \{(q_1, \in)\}$

Check whether the string $w = aacaa$ is accepted by empty stack or not ?

Solution :

We see that in each transition DPDA has at most one move. Initial configuration is $(q_0, aacaa, Z_0)$. Following are the possible moves.

$$(q_0, aacaa, Z_0) \rightarrow (q_0, acaa, aZ_0) \rightarrow (q_0, caa, aaZ_0) \rightarrow (q_1, aa, aaZ_0)$$

$$\downarrow$$

$$(q_1, \in, \in) \leftarrow (q_1, \in, Z_0) \leftarrow (q_1, a, aZ_0)$$

Hence, the string $w = aacaa$ is accepted by empty stack.

As we have discussed in earlier chapters that DFA and NFA are equivalent with respect to the language acceptance, but the same is not true for the PDA.

For example, language $L = \{ww^R : w \in (a \cup b)^*\}$ is accepted by nondeterministic PDA, can not by any deterministic PDA. A nondeterministic PDA can not be converted into equivalent deterministic PDA, but all DCFLs which are accepted by DPDA, are also accepted by NPDA. So, we say that deterministic PDA is a proper subset of nondeterministic PDA. Hence, the power of nondeterministic PDA is more as compared to deterministic PDA.

6.4 ACCEPTANCE OF LANGUAGE BY PDA

The language can be accepted by a Push Down Automata using two approaches.

1. **Acceptance by Final State :** The PDA accepts its input by consuming it and then it enters in the final state.

2. **Acceptance by empty stack :** On reading the input string from initial configuration for some PDA, the stack of PDA gets empty.

6.4.1 Equivalence of Empty Store and Final state acceptance

Theorem:

If $M_1 = (Q_1, \Sigma, \Gamma_1, \delta_1, p_1, Z_1, \phi)$ is a PDA accepting CFL L by empty store then there exists PDA $M_2 = (Q_2, \Sigma, \Gamma_2, \delta_2, p_2, Z_2, \{q_f\})$ which accepts L by final state.

Proof :

First we construct PDA M_2 based on PDA M_1 and then we prove that both accept L.

Step 1 : Construction of PDA M_2 based on given PDA M_1

Σ is same for both PDAs. We add a new initial state and a new final state with given PDA M_1.

So, $Q_2 = Q_1 \cup \{p_2 \cup q_f\}$

The stack alphabet Γ_2 of PDA M_2 contains one additional symbol Z_2 with Γ_1.

So, $\Gamma_2 = \Gamma_1 \cup \{Z_2\}$

The transition function δ_2 contains all the transitions of given PDA M_1 and two additional transitions (R_1 *and* R_3) as defined as follows :

$R_1 : \delta_2(p_2, \in, Z_2) = \{(p_1, Z_1 Z_2)\}$,

$R_2 : \delta_2(q, a, Z) = \delta_1(q, a, Z)$ for all (q, a, Z) in $Q_1 \times (\Sigma \cup \{\in\}) \times \Gamma_1$
(the original transitions of M_1), and

$R_3 : \delta_2(q, \in, Z_2) = \{(q_f, \in)\}$ for all $q \in Q_1$

By the R_1, M_2 moves from its initial ID $(p_2, \in, Z_2)$ to the initial ID of M_1. By R_2, M_2 uses all the transitions of M_1 after reaching the initial ID of M_1 and by using R_3 M_2 reaches the final state q_f.

The block diagram is shown in below figure.

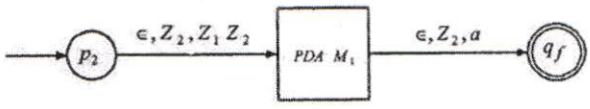


FIGURE : Block diagram of PDA M_2

Step 2 : The language accepted by PDA M_1 and PDA M_2

The behaviors of M_1 and M_2 are same except the two by $\in$ - moves defined by R_1 *and* R_3.

Let string $w \in L$ and accepted by M_1, then

$(p_1, w, Z_1) \vdash_{M_1}^{*} (q, \in, \in)$ where $q \in Q_1$ **(Result 1)**

For M_2, the initial ID is (p_2, w, Z_2) and it can be written as $(p_2, \in w \in, Z_2)$. So,

$(p_2, \in w \in, Z_2) \vdash_{M_2} (p_1, w, Z_1 Z_2)$ (This initial ID of M_1)

$\vdash_{M_2}^{*} (q, \in, Z_2)$ (by R_2 and Result 1)

$\vdash_{M_2}^{*} (q_f, \in, \alpha)$ $\alpha \in \Gamma_2^{*}$ (By R_3)

Thus, if M_1 accepts w, then M_2 also accepts it.

It means $L(M_2) \sqsubseteq L(M_1)$ **(Result 2)**

Let string $w \in L$ and accepted by PDA M_2, then

$(p_2, \in w \in, Z_2) \vdash_{M_2} (p_1, w, Z_1 Z_2)$ (By R_1) **(Result 3)**

$\vdash_{M_2}^{*} (q, \in, Z_2)$ (By R_2) **(Result 4)**

$\vdash_{M_2} (q_f, \in, \alpha)$ $\alpha \in \Gamma_2^{*}$ (By R_3)

Note : The Result 3 is the initial ID of M_1. The Result 4 shows the empty store for M_1 if symbol Z_2 is not there.

For M_1, the initial ID is (p_1, w, Z_1)

So, $(p_1, w, Z_1) \vdash_{M_2}^{*} (q, \in, \in)$, where $q \in Q_1$ (By Result 3 and Result 4) Thus, if M_2 accepts w, then M_1 also accepts it.

It means, $L(M_1) \subseteq L(M_2)$ **(Result 5)**

Therefore, $L = L(M_2) = L(M_1)$ (From Result 2 and Result 5)

Hence, the statement of theorem is proved.

Example: Consider a nondeterministic PDA $M_1 = (\{q_0\}, \{a,b\}, \{a,b,S\}, \delta, q_0, S, \phi)$ which accepts the language $L = \{a^n b^n : n \geq 1\}$ by empty store, where δ is defined as follows:

$\delta(q_0, \in, S) = \{(q_0, ab), (q_0, aSb)\}$ (Two possible moves),

$\delta(q_0, a, a) = \{(q_0, \in)\}$, and $\delta(q_0, b, b) = \{(q_0, \in)\}$

Construct an equivalent PDA M_2 which accepts L in final state and check whether string $w = aabb$ is accepted or not?

Solution : Following moves are carried out by PDA M_1 in order to accept $w = aabb$:

$$(q_0, aabb, S) \vdash (q_0, aabb, aSb)$$
$$\vdash (q_0, abb, Sb)$$
$$\vdash (q_0, abb, abb)$$
$$\vdash (q_0, bb, bb)$$
$$\vdash (q_0, b, b)$$
$$\vdash (q_0, \in, \in)$$

Hence, $(q_0, aabb, S) \vdash_{M_1}^{*} (q_0, \in, \in)$

Therefore, $w = aabb$ is accepted by M_1.

UNIT-5

TURING MACHINES

After going through this chapter, you should be able to understand :

- Turing Machine
- Design of TM
- Computable functions
- Recursively Enumerable languages
- Church's Hypothesis & Counter machine
- Types of Turing Machines

7.1 INTRODUCTION

The Turing machine is a generalized machine which can recognize all types of languages viz, regular languages (generated from regular grammar), context free languages (generated from context free grammar) and context sensitive languages (generated from context sensitive grammar). Apart from these languages, the Turing machine also accepts the language generated from unrestricted grammar. Thus, Turing machine can accept any generalized language. This chapter mainly concentrates on building the Turing machines for any language.

7.2 TURING MACHINE MODEL

The Turing machine model is shown in below figure . It is a finite automaton connected to read - write head with the following components :

- Tape
- Read - write head
- Control unit

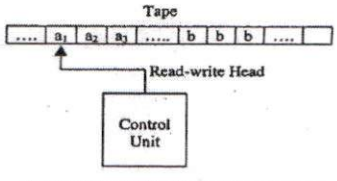

FIGURE : Turing machine model

Tape : It is a temporary storage and is divided into cells. Each cell can store the information of only one symbol. The string to be scanned will be stored from the left most position on the tape. The string to be scanned should end with infinite number of blanks.

Read - write head : The read - write head can read a symbol from where it is pointing to and it can write into the tape to where the read - write head points to.

Control Unit : The reading / writing from / to the tape is determined by the control unit. The different moves performed by the machine depends on the current scanned symbol and the current state. The read - write head can move either towards left or right i.e., movement can be on both the directions. The various moves performed by the machine are :

1. Change of state from one state to another state
2. The symbol pointing to by the read - write head can be replaced by another symbol.
3. The read - write head may move either towards left or towards right.

The Turing machine can be represented using various notations such as

- Transition table
- Instantaneous description
- Transition diagram

7.2.1 Transition Table

The table below shows the transition table for some Turing machine. Later sections describe how to obtain the transition table.

δ	Tape Symbols (Γ)				
States	a	b	X	Y	B
q_0	(q_1, X, R)	-	-	(q_3, Y, R)	-
q_1	(q_1, a, R)	(q_2, Y, L)	-	(q_1, Y, R)	-
q_2	(q_2, a, L)	-	(q_0, X, R)	(q_2, Y, L)	-
q_3	-	-	-	(q_3, Y, R)	(q_4, B, R)
q_4	-	-	-	-	-

Note that for each state q, there can be a corresponding entry for the symbol in Γ. In this table the symbols a and b are input symbols and can be denoted by the symbol Σ. Thus $\Sigma \subseteq \Gamma$ excluding the symbol B. The symbol B indicates a blank character and usually the string ends with infinite number of B's i. e., blank characters. The undefined entries indicate that there are no - transitions defined or there can be a transition to dead state. When there is a transition to the dead state, the machine halts and the input string is rejected by the machine. It is clear from the table that

$$\delta : Q \times \Gamma \text{ to } (Q \times \Gamma \times \{L, R\})$$

where $Q = \{q_0, q_1, q_2, q_3, q_4\}$; $\Sigma = \{a, b\}$

$\Gamma = \{a, b, X, Y, B\}$

q_0 is the initial state; B is a special symbol indicating blank character

$F = \{q_4\}$ which is the final state.

Thus, a Turing Machine M can be defined as follows.

Definition : The Turing Machine $M = (Q, \Sigma, \Gamma, \delta, q_0, B, F)$ where

Q is set of finite states

Σ is set of input alphabets

Γ is set of tape symbols

δ is transition function $Q \times \Gamma$ to $(Q \times \Gamma \times \{L, R\})$

q_0 is the initial state

B is a special symbol indicating blank character

$F \subseteq Q$ is set of final states.

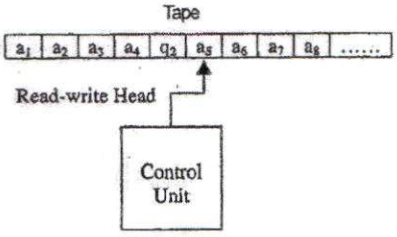
7.2.2 Instantaneous description (ID)

Unlike the ID described in PDA, in Turing machine (TM), the ID is defined on the whole string (not on the string to be scanned) and the current state of the machine.

Definition :

An ID of TM is a string in $\alpha q \beta$, where q is the current state, $\alpha \beta$ is the string made from tape symbols denoted by Γ i. e., α and $\beta \in \Gamma^*$. The read - write head points to the first character of the substring β. The initial ID is denoted by $q\alpha\beta$ where q is the start state and the read - write head points to the first symbol of α from left. The final ID is denoted by $\alpha\beta qB$ where $q \in F$ is the final state and the read - write head points to the blank character denoted by B.

Example : Consider the snapshot of a Turing machine



In this machine, each $a_i \in \Gamma$ (i.e., each a_i belongs to the tape symbol). In this snapshot, the symbol a_5 is under read - write head and the symbol towards left of a_5 i.e., q_2 is the current state. Note that, in the Turing machine, the symbol immediately towards left of the read - write head will be the current state of the machine and the symbol immediately towards right of the state will be the next symbol to be scanned. So, in this case an ID is denoted by

$$a_1a_2a_3a_4q_2a_5a_6a_7a_8.....$$

where the substring $a_1a_2a_3a_4$ towards left of the state q_2 is the left sequence, the substring $a_5a_6a_7a_8$..... towards right of the state q_2 is the right sequence and q_2 is the current state of the machine. The symbol a_5 is the next symbol to be scanned.

Assume that the current ID of the Turing machine is $a_1a_2a_3a_4q_2a_5a_6a_7a_8$..... as shown in snapshot of example.

Suppose, there is a transition $\delta(q_2, a_5) = (q_3, b_1, R)$

It means that if the machine is in state q_2 and the next symbol to be scanned is a_5, then the machine enters into state q_3 replacing the symbol a_5 by b_1 and R indicates that the read - write head is moved one symbol towards right. The new configuration obtained is

$$a_1a_2a_3a_4b_1q_3a_6a_7a_8.....$$

This can be represented by a move as $a_1a_2a_3a_4q_2a_5a_6a_7a_8.... \vdash a_1a_2a_3a_4b_1q_3a_6a_7a_8.....$

Similarly if the current ID of the Turing machine is $a_1a_2a_3a_4q_2a_5a_6a_7a_8.....$

and there is a transition

$$\delta(q_2, a_5)=(q_1, c_1, L)$$

means that if the machine is in state q_2 and the next symbol to be scanned is a_5, then the machine enters into state q_1 replacing the symbol a_5 by c_1 and L indicates that the read - write head is moved one symbol towards left. The new configuration obtained is

$$a_1a_2a_3q_1a_4c_1a_6a_7a_8.....$$

This can be represented by a move as $a_1a_2a_3a_4q_2a_5a_6a_7a_8\ldots. \vdash a_1a_2a_3q_1a_4c_1a_6a_7a_8\ldots.$

This configuration indicates that the new state is q_1, the next input symbol to be scanned is a_4. The actions performed by TM depends on

1. The current state.
2. The whole string to be scanned
3. The current position of the read - write head

The action performed by the machine consists of

1. Changing the states from one state to another
2. Replacing the symbol pointed to by the read - write head
3. Movement of the read - write head towards left or right.

7.2.3 The move of Turing Machine M can be defined as follows

Definition : Let $M = (Q, \Sigma, \Gamma, \delta, q_0, B, F)$ be a TM. Let the ID of M be $a_1a_2a_3\ldots\ldots a_{k-1}qa_ka_{k+1}\ldots\ldots a_n$ where $a_j \in \Gamma$ for $1 \le j \le n-1$, $q \in Q$ is the current state and a_k as the next symbol to scanned. If there is a transition $\delta(q, a_k) = (p, b, R)$

then the move of machine M will be $a_1a_2a_3\ldots\ldots a_{k-1}qa_ka_{k+1}\ldots\ldots a_n \vdash a_1a_2a_3\ldots\ldots a_{k-1}bpa_{k+1}\ldots\ldots a_n$

If there is a transition $\delta(q, a_k) = (p, b, L)$

then the move of machine M will be

$$a_1a_2a_3\ldots\ldots a_{k-1}qa_ka_{k+1}\ldots\ldots a_n \vdash a_1a_2a_3\ldots\ldots a_{k-2}pa_{k-1}ba_{k+1}\ldots\ldots a_n$$

7.2.4 Acceptance of a language by TM

The language accepted by TM is defined as follows.

Definition :

Let $M = (Q, \Sigma, \Gamma, \delta, q_0, B, F)$ be a TM. The language L(M) accepted by M is defined as

$$L(M) = \{w \mid q_0w \vdash^* \alpha_1\ p\ \alpha_2 \text{ where } w \in \Sigma^*, p \in F \text{ and } \alpha_1, \alpha_2 \in \Gamma^*\}$$

i.e., set of all those words w in Σ^* which causes M to move from start state q_0 to the final state p. The language accepted by TM is called recursively enumerable language.

The string w which is the string to be scanned, should end with infinite number of blanks. Initially, the machine will be in the start state q_0 with read - write head pointing to the first symbol of w from left. After some sequence of moves, if the Turing machine enters into the final state and halts, then we say that the string w is accepted by Turing machine.

7.2.5 Differences between TM and PDA

Push Down Automa :

1. A PDA is a nondeterministic finite automaton coupled with a stack that can be used to store a string of arbitrary length.
2. The stack can be read and modified only at its top.
3. A PDA chooses its next move based on its current state, the next input symbol and the symbol at the top of the stack.
4. There are two ways in which the PDA may be allowed to signal acceptance. One is by entering an accepting state, the other by emptying its stack.
5. ID consisting of the state, remaining input and stack contents to describe the "current condition" of a PDA.
6. The languages accepted by PDA's either by final state or by empty stack, are exactly the context - free languages.
7. A PDA languages lie strictly between regular languages and CSL's.

Turing Machines :

1. The TM is an abstract computing machine with the power of both real computers and of other mathematical definitions of what can be computed.
2. TM consists of a finite - state control and an infinite tape divided into cells.
3. TM makes moves based on its current state and the tape symbol at the cell scanned by the tape head.
4. The blank is one of tape symbols but not input symbol.
5. TM accepts its input if it ever enters an accepting state.
6. The languages accepted by TM's are called Recursively Enumerable (RE) languages.
7. Instantaneous description of TM describes current configuration of a TM by finite - length string.
8. Storage in the finite control helps to design a TM for a particular language.
9. A TM can simulate the storage and control of a real computer by using one tape to store all the locations and their contents.

7.3 CONSTRUCTION OF TURING MACHINE (TM)

In this section, we shall see how TMs can be constructed.

Example 1 : Obtain a Turing machine to accept the language $L = \{ 0^n 1^n \mid n \geq 1 \}$.

Solution : Note that n number of 0's should be followed by n number of 1's. For this let us take an example of the string $w = 00001111$. The string w should be accepted as it has four zeroes followed by equal number of 1's.

Step 3 : In state q_1, if the input symbol to be scanned is a 1, then replace 1 by Y, change the state to q_2 and move the pointer towards left. The transition for this can be of the form

$$\delta(q_1,1)=(q_2,Y,L)$$

and the following configuration is obtained.

XXX0YYY1

↑

q_2

Note that the pointer is moved towards left. This is because, a zero is replaced by X and the corresponding 1 is replaced by Y. Now, we have to scan for the left most 0 again and so, the pointer was move towards left.

Step 4 : Note that to obtain leftmost zero, we need to obtain right most X first. So, we scan for the right most X. During this process we may encounter Y's and 0's . Replace Y by Y, 0 by 0, remain in state q_2 only and move the pointer towards left. The transitions for this can be of the form

$$\delta(q_2,Y)=(q_2,Y,L)$$

$$\delta(q_2,0)=(q_2,0,L)$$

The following configuration is obtained

XXX0YYY1

↑

q_2

Step 5 : Now, we have obtained the right most X. To get leftmost 0, replace X by X, change the state to q_0 and move the pointer towards right. The transition for this can be of the form

$$\delta(q_2,X)=(q_0,X,R)$$

and the following configuration is obtained

XXX0YYY1

↑

q_0

Now, repeating the steps 1 through 5, we get the configuration shown below :

XXXXYYYY

↑

q_0

Step 6 : In state q_0, if the scanned symbol is Y, it means that there are no more 0's. If there are no zeroes we should see that there are no 1's. For this we change the state to q_1, replace Y by Y and move the pointer towards right. The transition for this can be of the form

$$\delta(q_0,Y)=(q_3,Y,R)$$

and the following configuration is obtained

XXXXYYYY

↑

q_3

In state q_3, we should see that there are only Ys and no more 1's. So, as we can replace Y by Y and remain in q_3 only. The transition for this can be of the form

$$\delta(q_3,Y)=(q_3,Y,R)$$

Repeatedly applying this transition, the following configuration is obtained.

XXXXYYYYB

↑

q_3

Note that the string ends with infinite number of blanks and so, in state q_3 if we encounter the symbol B, means that end of string is encountered and there exists n number of 0's ending with n number of 1's. So, in state q_3, on input symbol B, change the state to q_4, replace B by B and move the pointer towards right and the string is accepted. The transition for this can be of the form $\delta(q_3,B)=(q_4,B,R)$

The following configuration is obtained

XXXXYYYYBB

↑

q_4

So, the Turing machine to accept the language $L=\{a^n\ b^n \mid n\geq 1\}$

is given by $M=(Q,\Sigma,\Gamma,\delta,q_0,B,F)$

where

$Q=\{q_0, q_1, q_2, q_3\}$; $\Sigma=\{0,1\}$; $\Gamma=\{0, 1, X, Y, B\}$

$q_0 \in Q$ is the start state of machine; $B \in \Gamma$ is the blank symbol.

$F=\{q_4\}$ is the final state.

δ is shown below.

$$\delta(q_0, 0) = (q_1, X, R)$$

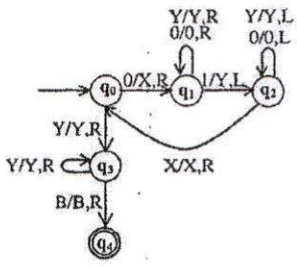
$$\delta(q_1,0)=(q_1,0,R)$$

$$\delta(q_1, Y) = (q_1, Y, R)$$
$$\delta(q_1, 1) = (q_2, Y, L)$$
$$\delta(q_2, Y) = (q_2, Y, L)$$
$$\delta(q_2, 0) = (q_2, 0, L)$$
$$\delta(q_2, X) = (q_0, X, R)$$
$$\delta(q_0, Y) = (q_3, Y, R)$$
$$\delta(q_3, Y) = (q_3, Y, R)$$
$$\delta(q_3, B) = (q_4, B, R)$$

The transitions can also be represented using tabular form as shown below.

δ	Tape Symbols (Γ)				
States	0	1	X	Y	B
q_0	(q_1, X, R)	-	-	(q_3, Y, R)	-
q_1	$(q_1, 0, R)$	(q_2, Y, L)	-	(q_1, Y, R)	-
q_2	$(q_2, 0, L)$	-	(q_0, X, R)	(q_2, Y, L)	-
q_3	-	-	-	(q_3, Y, R)	(q_4, B, R)
q_4	-	-	-	-	-

The transition table shown above can be represented as transition diagram as shown below :



To accept the string :

The sequence of moves or computations (IDs) for the string 0011 made by the Turing machine are shown below :

Initial ID

$q_0 0011$ $\vdash Xq_1 011$ $\vdash X0q_1 11$

$\vdash Xq_2 0Y1$ $\vdash q_2 X0Y1$

$\vdash Xq_0 0Y1$ $\vdash XXq_1 Y1$

$\vdash XXYq_1 1$ $\vdash XXq_2 YY$

$\vdash Xq_2 XYY$ $\vdash XXq_0 YY$

$\vdash XXYq_3 Y$ $\vdash XXYYq_3$

$\vdash XXYYBq_4$

(Final ID)

Example 2 : Obtain a Turing machine to accept the language $L(M) = \{ 0^n 1^n 2^n \mid n \geq 1 \}$

Solution : Note that n number of 0's are followed by n number of 1's which in turn are followed by n number of 2's. In simple terms, the solution to this problem can be stated as follows :

Replace first n number of 0's by X's, next n number of 1's by Y's and next n number of 2's by Z's. Consider the situation where in first two 0's are replaced by X's , next immediate two 1's are replaced by Y's and next two 2's are replaced by Z's as shown in figure 1(a).

XX00YY11ZZ22	XXX0YY11ZZ22	XXX0YY11ZZ22
↑	↑	↑
q_0	q_1	q_1
(a)	(b)	(c)

FIGURE 1 : Various Configurations

Now, with figure 1(a). a as the current configuration, let us design the Turing machine. In state q_0, if the next scanned symbol is 0 replace it by X, change the state to q_1 and move the pointer towards right and the situation shown in figure 1(b) is obtained . The transition for this can be of the form

$$\delta(q_0, 0) = (q_1, X, R)$$

In state q_1, we have to search for the leftmost 1. It is clear from figure 1(b) that, when we are searching for the symbol 1, we may encounter the symbols 0 or Y. So, replace 0 by 0 , Y by Y and move the pointer towards right and remain in state q_1 only. The transitions for this can be of the form

$$\delta(q_1, 0) = (q_1, 0, R)$$

$$\delta(q_1, Y) = (q_1, Y, R)$$

The configuration shown in figure 1(c) is obtained. In state q_1, on encountering 1 change the state to q_2, replace 1 by Y and move the pointer towards right. The transition for this can be of the form

$$\delta(q_1,1)=(q_2,Y,R)$$

and the configuration shown in figure 2(a) is obtained

XXX0YYY1ZZ22	XXX0YYY1ZZ22	XXX0YYY1ZZZ2
↑	↑	↑
q_2	q_2	q_3
(a)	(b)	(c)

FIGURE 2 : Various Configurations

In state q_2, we have to search for the leftmost 2. It is clear from figure 2(a) that, when we are searching for the symbol 2, we may encounter the symbols 1 or Z. So, replace 1 by 1, Z by Z and move the pointer towards right and remain in state q_2 only and the configuration shown in figure 2(b) is obtained. The transitions for this can be of the form

$$\delta(q_2,1)=(q_2,1,R)$$
$$\delta(q_2,Z)=(q_2,Z,R)$$

In state q_2, on encountering 2, change the state to q_3, replace 2 by Z and move the pointer towards left. The transition for this can be of the form

$$\delta(q_2,2)=(q_3,Z,L)$$

and the configuration shown in figure 2(c) is obtained. Once the TM is in state q_3, it means that equal number of 0's, 1's and 2's are replaced by equal number of X's, Y's and Z's respectively. At this point, next we have to search for the rightmost X to get leftmost 0. During this process, it is clear from figure 2(c) that the symbols such as Z's, 1,s, Y's, 0's and X are scanned respectively one after the other. So, replace Z by Z, 1 by 1, Y by Y, 0 by 0, move the pointer towards left and stay in state q_3 only. The transitions for this can be of the form

$$\delta(q_3,Z)=(q_3,Z,L)$$
$$\delta(q_3,1)=(q_3,1,L)$$
$$\delta(q_3,Y)=(q_3,Y,L)$$
$$\delta(q_3,0)=(q_3,0,L)$$

Only on encountering X, replace X by X, change the state to q_0 and move the pointer towards right to get leftmost 0. The transition for this can be of the form

$$\delta(q_3,X)=(q_0,X,R)$$

All the steps shown above are repeated till the following configuration is obtained.

XXXXYYYYZZZZ

↑

q_0

In state q_0, if the input symbol is Y, it means that there are no 0's . If there are no 0's we should see that there are no 1's also. For this to happen change the state to q_4, replace Y by Y and move the pointer towards right. The transition for this can be of the form

$$\delta(q_0, Y) = (q_4, Y, R)$$

In state q_4 search for only Y's, replace Y by Y, remain in state q_4 only and move the pointer towards right. The transition for this can be of the form

$$\delta(q_4, Y) = (q_4, Y, R)$$

In state q_4, if we encounter Z, it means that there are no 1's and so we should see that there are no 2's and only Z's should be present. So, on scanning the first Z, change the state to q_5, replace Z by Z and move the pointer towards right. The transition for this can be of the form

$$\delta(q_4, Z) = (q_5, Z, R)$$

But, in state q_5 only Z's should be there and no more 2's. So, as long as the scanned symbol is Z, remain in state q_5, replace Z by Z and move the pointer towards right. But, once blank symbol B is encountered change the state to q_6, replace B by B and move the pointer towards right and say that the input string is accepted by the machine. The transitions for this can be of the form

$$\delta(q_5, Z) = (q_5, Z, R)$$

$$\delta(q_5, B) = (q_6, B, R)$$

where q_6 is the final state.

So, the TM to recognize the language $L = \{ 0^n 1^n 2^n \mid n \geq 1 \}$ is given by

$$M = (Q, \Sigma, \Gamma, \delta, q_0, B, F)$$

where

$Q = \{q_0, q_1, q_2, q_3, q_4, q_5, q_6\}$; $\Sigma = \{0, 1, 2\}$

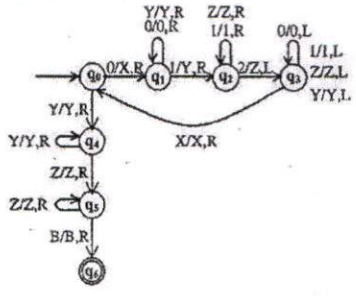
$\Gamma = \{0, 1, 2, X, Y, Z, B\}$; q_0 is the initial state

B is blank character; $F = \{ q_6 \}$ is the final state

δ is shown below using the transition table.

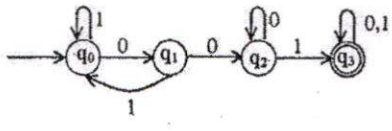
	Γ						
States	0	1	2	Z	Y	X	B
q_0	q_1, X, R				q_4, Y, R		
q_1	q_1, 0, R	q_2, Y,R			q_1, Y,R		
q_2		q_2, 1,R	q_3, Z,L	q_2, Z,R			
q_3	q_3, 0,L	q_3, 1,L		q_1, Z,L	q_3, Y,L	q_0, X,R	
q_4				q_4, Z,R	q_4, Y,R		
q_5				q_5, Z,R			(q_6, B, R)
q_6							

The transition diagram for this can be of the form



Example 3 : Obtain a TM to accept the language $L = \{w \mid w \in (0+1)^*\}$ containing the substring 001.

Solution : The DFA which accepts the language consisting of strings of 0's and 1's having a sub string 001 is shown below :



The transition table for the DFA is shown below :

	0	1
q_0	q_1	q_0
q_1	q_2	q_0
q_2	q_2	q_3
q_3	q_3	q_3

We have seen that any language which is accepted by a DFA is regular. As the DFA processes the input string from left to right in only one direction, TM also processes the input string in only one direction (unlike the previous examples, where the read - write header was moving in both the directions). For each scanned input symbol (either 0 or 1), in whichever state the DFA was in, TM also enters into the same states on same input symbols, replacing 0 by 0 and 1 by 1 and the read - write head moves towards right. So, the transition table for DFA and TM remains same (the format may be different. It is evident in both the transition tables). So, the transition table for TM to recognize the language consisting of 0's and 1's with a substring 001 is shown below :

	0	1	B
q_0	q_1,0, R	q_0, 1, R	-
q_1	q_2, 0, R	q_0, 1, R	-
q_2	q_2, 0, R	q_3, 1, R	-
q_3	q_3, 0, R	q_3, 1, R	q_4, B, R
q_4			

The TM is given by

$$M = (Q, \Sigma, \Gamma, \delta, q_0, B, F)$$

where

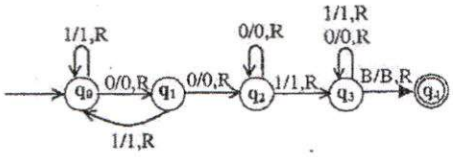
$Q = \{q_0, q_1, q_2, q_3, q_4\}$; $\Sigma = \{0, 1\}$

$\Gamma = \{0, 1\}$; δ – is defined already

q_0 is the initial state ; B blank character

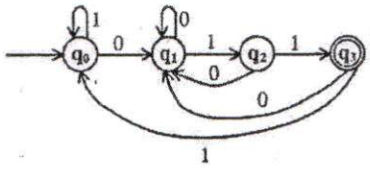
$F = \{q_4\}$ is the final state

The transition diagram for this is shown below.



Example 4 : Obtain a Turing machine to accept the language containing strings of 0's and 1's ending with 011.

Solution : The DFA which accepts the language consisting of strings of 0's and 1's ending with the string 001 is shown below :



The transition table for the DFA is shown below :

δ	0	1
q_0	q_1	q_0
q_1	q_1	q_2
q_2	q_1	q_3
q_3	q_1	q_0

We have seen that any language which is accepted by a DFA is regular. As the DFA processes the input string from left to right in only one direction, TM also processes the input string in only one direction. For each scanned input symbol (either 0 or 1), in whichever state the DFA was in, TM also enters into the same states on same input symbols, replacing 0 by 0 and 1 by 1 and the read - write head moves towards right. So, the transition table for DFA and TM remains same (the format may be different. It is evident in both the transition tables). So, the transition table for TM to recognize the language consisting of 0's and 1's ending with a substring 001 is shown below :

δ	0	1	B
q_0	q_1, 0, R	q_0, 1, R	-
q_1	q_1, 0, R	q_2, 1, R	-
q_2	q_1, 0, R	q_3, 1, R	-
q_3	q_1, 0, R	q_0, 1, R	q_4, B, R
q_4	-	-	-

The TM is given by $M = (Q, \Sigma, \Gamma, \delta, q_0, B, F)$
where

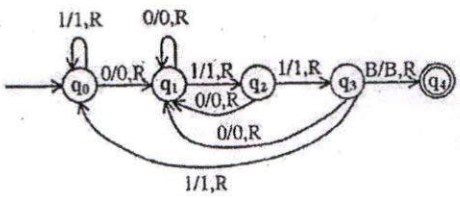
$Q = \{q_0, q_1, q_2, q_3\}$; $\Sigma = \{0, 1\}$; $\Gamma = \{0, 1\}$

δ – is defined already

q_0 is the initial state ; B does not appear

$F = \{q_4\}$ is the final state

The transition diagram for this is shown below :

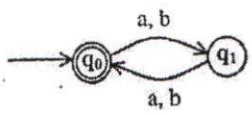


Example 5 : Obtain a Turing machine to accept the language

$L = \{w | w \text{ is even and } \Sigma = \{a, b\}\}$

Solution :

The DFA to accept the language consisting of even number of characters is shown below.



The transition table for the DFA is shown below :

	a	b
q_0	q_1	q_1
q_1	q_0	q_0

We have seen that any language which is accepted by a DFA is regular. As the DFA processes the input string from left to right in only one direction, TM also processes the input string in only one direction. For each scanned input symbol (either a or b), in whichever state the DFA was in, TM also enters into the same states on same input symbols, replacing a by a and b by b and the read - write head moves towards right. So, the transition table for DFA and TM remains same (the format may be different). So, the transition table for TM to recognize the language consisting of a's and b's having even number of symbols is shown below :

δ	a	b	B
q_0	q_1, a, R	q_1, b, R	q_2, B, R
q_1	q_0, a, R	q_0, b, R	-
q_2	-	-	-

The TM is given by

$$M = (Q, \Sigma, \Gamma, \delta, q_0, B, F)$$

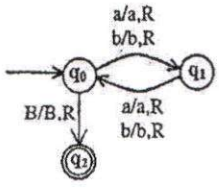
where

$Q = \{ q_0, q_1 \}$; $\Sigma = \{a, b\}$; $\Gamma = \{a, b\}$

δ – is defined already ; q_0 is the initial state

B does not appear ; $F = \{ q_2 \}$ is the final state

The transition diagram of TM is given by



Example 6 : Obtain a Turing machine to accept a palindrome consisting of a's and b's of any length.

Solution : Let us assume that the first symbol on the tape is blank character B and is followed by the string which in turn ends with blank character B. Now, we have to design a Turing machine which accepts the string, provided the string is a palindrome. For the string to be a palindrome, the first and the last character should be same. The second character and last but one character in the string should be same and so on. The procedure to accept only string of palindromes is shown below. Let q0 be the start state of Turing machine.

Step 1 : Move the read - write head to point to the first character of the string. The transition for this can be of the form $\delta(q_0, B) = (q_1, B, R)$

Step 2 : In state q_1, if the first character is the symbol a, replace it by B and change the state to q_2 and move the pointer towards right. The transition for this can be of the form

$$\delta(q_1, a) = (q_2, B, R)$$

Now, we move the read - write head to point to the last symbol of the string and the last symbol should be a. The symbols scanned during this process are a's, b's and B. Replace a by a, b by b and move the pointer towards right. The transitions defined for this can be of the form

$$\delta(q_2, a) = (q_2, a, R)$$

$$\delta(q_2, b) = (q_2, b, R)$$

But, once the symbol B is encountered, change the state to q_3, replace B by B and move the pointer towards left. The transition defined for this can be of the form

$$\delta(q_2, B) = (q_3, B, L)$$

In state q_3, the read - write head points to the last character of the string. If the last character is a, then change the state to q_4, replace a by B and move the pointer towards left. The transitions defined for this can be of the form

$$\delta(q_3, a) = (q_4, B, L)$$

At this point, we know that the first character is a and last character is also a. Now, reset the read - write head to point to the first non blank character as shown in step5.

In state q_3, if the last character is B (blank character), it means that the given string is an odd palindrome. So, replace B by B change the state to q_7 and move the pointer towards right. The transition for this can be of the form

$$\delta(q_3, B) = (q_7, B, R)$$

Step 3 : If the first character is the symbol b, replace it by B and change the state from q_1 to q_5 and move the pointer towards right. The transition for this can be of the form

$$\delta(q_1, b) = (q_5, B, R)$$

Now, we move the read - write head to point to the last symbol of the string and the last symbol should be b. The symbols scanned during this process are a's, b's and B. Replace a by a, b by b and move the pointer towards right. The transitions defined for this can of the form

$$\delta(q_5, a) = (q_5, a, R)$$
$$\delta(q_5, b) = (q_5, b, R)$$

But, once the symbol B is encountered, change the state to q_6, replace B by B and move the pointer towards left. The transition defined for this can be of the form

$$\delta(q_5, B) = (q_6, B, L)$$

In state q_6, the read - write head points to the last character of the string. If the last character is b, then change the state to q_5, replace b by B and move the pointer towards left. The transitions defined for this can be of the form

$$\delta(q_6, b) = (q_4, B, L)$$

At this point, we know that the first character is b and last character is also b. Now, reset the read - write head to point to the first non blank character as shown in step 5.

In state q_6, If the last character is B (blank character), it means that the given string is an odd palindrome. So, replace B by B, change the state to q_7 and move the pointer towards right. The transition for this can be of the form

$$\delta(q_6, B) = (q_7, B, R)$$

Step 4 : In state q_1, if the first symbol is blank character (B), the given string is even palindrome and so change the state to q_7, replace B by B and move the read - write head towards right. The transition for this can be of the form

$$\delta(q_1, B) = (q_7, B, R)$$

Step 5 : Reset the read - write head to point to the first non blank character. This can be done as shown below.

If the first symbol of the string is a, step 2 is performed and if the first symbol of the string is b, step 3 is performed. After completion of step 2 or step 3, it is clear that the first symbol and the last symbol match and the machine is currently in state q_4. Now, we have to reset the read - write head to point to the first nonblank character in the string by repeatedly moving the head towards left and remain in state q_4. During this process, the symbols encountered may be a or b or B (blank character). Replace a by a, b by b and move the pointer towards left. The transitions defined for this can be of the form $\delta(q_4, a) = (q_4, a, L)$

$$\delta(q_4, b) = (q_4, b, L)$$

But, if the symbol B is encountered , change the state to q_1, replace B by B and move the pointer towards right. the transition defined for this can be of the form

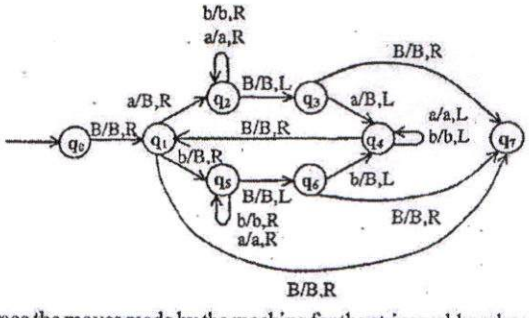
$$\delta(q_4, B) = (q_1, B, R)$$

After resetting the read - write head to the first non - blank character, repeat through step 1.

So, the TM to accept strings of palindromes over { a, b } is given by $M = (Q, \Sigma, \delta, q_0, B, F)$ where $Q = \{q_0, q_1, q_2, q_3, q_4, q_5, q_6, q_7\}$; $\Sigma = \{a, b\}$; $\Gamma = \{a, b, B\}$; q_0 is the initial state B is the blank character ; $F = \{q_7\}$; δ is shown below using the transition table

	Γ		
δ	a	b	B
q_0	-	-	q_1, B, R
q_1	q_2, B, R	q_3, B, R	q_7, B, R
q_2	q_2, a, R	q_2, b, R	q_3, B, L
q_3	q_4, B, L	-	q_7, B, R
q_4	q_4, a, L	q_4, b, L	q_1, B, R
q_5	q_5, a, R	q_5, b, R	q_6, B, L
q_6	-	q_4, B, L	q_7, B, R
q_7	-	-	-

The transition diagram to accept palindromes over { a, b } is given by

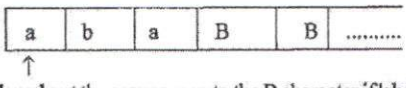


The reader can trace the moves made by the machine for the strings abba, aba and aaba and is left as an exercise.

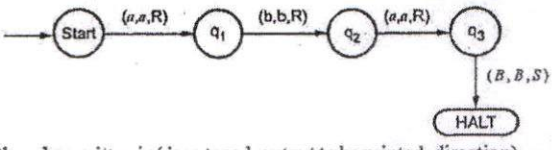
Example 7 : Construct a Turing machine which accepts the language of aba over $\Sigma = \{a, b\}$.

Solution : This TM is only for L = { aba }

We will assume that on the input tape the string 'aba' is placed like this

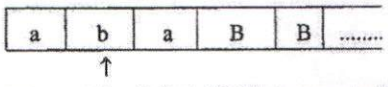


The tape head will read out the sequence upto the B character if 'aba' is readout the TM will halt after reading B.

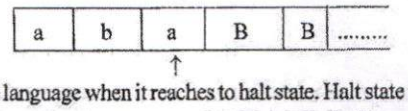


The triplet along the edge written is (input read, output to be printed, direction)

Let us take the transition between start state and q_1 is (a, a, R) that is the current symbol read from the tape is a then as a output a only has to be printed on the tape and then move the tape head to the right. The tape will look like this



Again the transition between q_1 and q_2 is (b, b, R). That means read b, print b and move right. Note that as tape head is moving ahead the states are getting changed.



The TM will accept the language when it reaches to halt state. Halt state is always a accept state for any TM. Hence the transition between q_3 and halt is (B, B, S). This means read B, print B and stay there or there is no move left or right. Eventhough we write (B, B, L) or (B, B, R) it is equally correct. Because after all the complete input is already recognized and now we simply want to enter into a accept state or final state. Note that for invalid inputs such as abb or ab or bab ..... there is either no path reaching to final state and for such inputs the TM gets stucked in between. This indicates that these all invalid inputs can not be recognized by our TM.

The same TM can be represented by another method of transition table

	a	b	B
Start	(q_1, a, R)	-	-
q_1	-	(q_2, b, R)	-
q_2	(q_3, a, R)	-	-
q_3	-	-	(HALT, B, S)
HALT	-	-	-

In the given transition table, we write the triplet in each row as :

(Next state, output to be printed, direction)

Thus TM can be represented by any of these methods.

Example 8 : Design a TM that recognizes the set $L = \{0^{2n}1^n \mid n \geq 0\}$.

Solution : Here the TM checks for each one whether two 0's are present in the left side. If it match then only it halts and accept the string.

The transition graph of the TM is ,

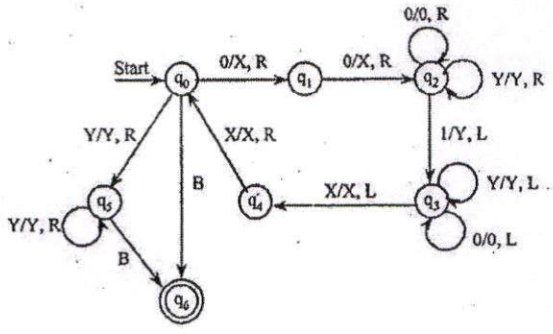


FIGURE : Turing Machine for the given language $L = \{0^{2n}1^n \mid n \geq 0\}$

Example 11 : What does the Turing Machine described by the 5 - tuples,

$(q_0,0,q_0,1,R),(q_0,1,q_1,0,r),(q_0,B,q_2,B,R)$,

$(q_1,0,q_1,0,R)$, $(q_1,1,q_0,1,R)$ *and* (q_1,B,q_2,B,R) .Do when given a bit string as input ?

Solution : The transition diagram of the TM is ,

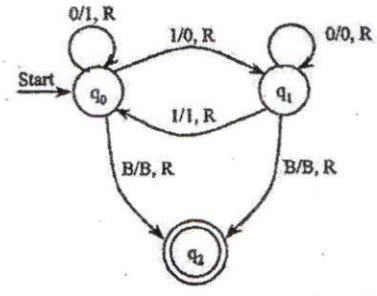

FIGURE : Transition Diagram for the given TM

The TM here reads an input and starts inverting 0's to 1's and 1's to 0's till the first 1. After it has inverted the first 1, it read the input symbol and keeps it as it is till the next 1. After encountering the 1 it starts repeating the cycle by inverting the symbol till next 1. It halts when it encounters a blank symbol.

7.4 COMPUTABLE FUNCTIONS

A Turing machine is a language acceptor which checks whether a string x is accepted by a language L. In addition to that it may be viewed as computer which performs computations of functions from integers to integers. In traditional approach an integer is represented in unary, an integer $i \geq 0$ is represented by the string 0^i.

Example 1 : 2 is represented as 0^2. If a function has k arguments, $i_1, i_2, \ldots\ldots i_k$, then these integers are initially placed on the tape separated by 1's, as $0^{i_1}10^{i_2}1 \ldots\ldots 10^{i_k}$.

If the TM halts (whether in or not in an accepting state) with a tape consisting of 0's for some m, then we say that $f(i_1, i_2, \ldots\ldots i_k) = m$, where f is the function of k arguments computed by this Turing machine.

$\delta(q_4,1) = (q_4, B, L)$

$\delta(q_4,0) = (q_4, 0, L)$

$\delta(q_4,0) = (q_6, 0, R)$

If in state q_2 a B is encountered before a 0, we have situation (i) described above. Enter state q_4 and move left, changing all 1's to B 's until encountering a 'B'. This B is changed back to a 0, state q_6 is entered, and M halts.

6. $\delta(q_0,1) = (q_5, B, R)$

$\delta(q_5,0) = (q_5, B, R)$

$\delta(q_5,1) = (q_5, B, R)$

$\delta(q_5,B) = (q_6, B, R)$

If in state q_0 a 1 is encountered instead of a 0, the first block of 0's has been exhausted, as in situation (ii) above. M enters state q_5 to erase the rest of the tape, then enters q_6 and halts.

Example 4 : Design a TM which computes the addition of two positive integers.

Solution : Let TM $M = (Q, \{0, 1, \#\}, \delta, s)$ computes the addition of two positive integers m and n. It means, the computed function f(m, n) defined as follows :

$$f(m,n) = \begin{cases} m+n (If\ m, n \geq 1) \\ 0 \qquad (m = n = 0) \end{cases}$$

1 on the tape separates both the numbers m and n. Following values are possible for m and n.

1. $m = n = 0$ (# 1 # ..... is the input),
2. m = 0 and $n \neq 0$ (#10*# ..... is the input),
3. $m \neq 0$ and n = 0 (#0*1# ... is the input), and
4. $m \neq 0$ and $n \neq 0$ (#0*10*# ..... is the input)

Several techniques are possible for designing of M, some are as follows :

(a) M appends (writes) m after n and erases the m from the left end.

(b) M writes 0 in place of 1 and erases one zero from the right or left end . This is possible in case of $n \neq 0$ or $m \neq 0$ only. If m =0 or n = 0 then 1 is replaced by #.

We use techniques (b) given above. M is shown in below figure.

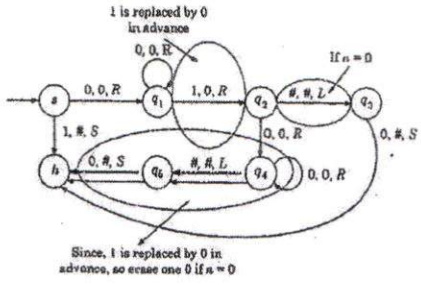

FIGURE : TM for addition of two positive integers

7.5 RECURSIVELY ENUMERABLE LANGUAGES

A language L over the alphabet Σ is called recursively enumerable if there is a TM M that accept every word in L and either rejects (crashes) or loops for every word in language L' the complement of L.

Accept (M) = L

Reject (M) + Loop (M) = L'

When TM M is still running on some input (of recursively enumerable languages) we can never tell whether M will eventually accept if we let it run for long time or M will run forever (in loop).

Example : Consider a language (a + b) * bb (a + b) *.

TM for this language is ,

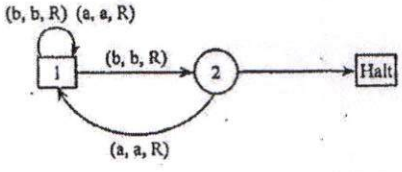

FIGURE : Turing Machine for (a + b) * bb (a + b) *

Here the inputs are of three types.

1. All words with bb = accepts (M) as soon as TM sees two consecutive b's it halts.
2. All strings without bb but ending in b = rejects (M). When TM sees a single b, it enters state2. If the string is ending with b, TM will halt at state 2 which is not accepting state. Hence it is rejected.
3. All strings without bb ending in 'a' or blank 'B' = loop (M) here when the TM sees last a it enters state 1. In this state on blank symbol it loops forever.

Recursive Language

A language L over the alphabet Σ is called recursive if there is a TM M that accepts every word in L and rejects every word in L' i. e.,

accept (M) = L
reject (M) = L'
loop (M) = ϕ.

Example :Consider a language b (a + b) * . It is represented by TM as :

FIGURE : Turing Machine for b (a + b) *

This TM accepts all words beginning with 'b' because it enters halt state and it rejects all words beginning with a because it remains in start state which is not accepting state.

A language accepted by a TM is said to be recursively enumerable languages. The subclass of recursively enumberable sets (r. e) are those languages of this class are said to be recursive sets or recursive language.

7.6 CHURCH'S HYPOTHESIS

According to church's hypothesis, all the functions which can be defined by human beings can be computed by Turing machine. The Turing machine is believed to be ultimate computing machine.

The church's original statement was slightly different because he gave his thesis before machines were actually developed. He said that any machine that can do certain list of operations will be able to perform all algorithms. TM can perform what church asked, so they are possibly the machines which church described.

Church tied both recursive functions and computable functions together. Every partial recursive function is computable on TM. Computer models such as RAM also give rise to partial recursive functions. So they can be simulated on TM which confirms the validity of churches hypothesis.

Important of church's hypothesis is as follows .

1. First we will prove certain problems which cannot be solved using TM.

2. If churches thesis is true this implies that problems cannot be solved by any computer or any programming languages we might every develop.

3. Thus in studying the capabilities and limitations of Turing machines we are indeed studying the fundamental capabilities and limitations of any computational device we might even construct.

It provides a general principle for algorithmic computation and, while not provable, gives strong evidence that no more powerful models can be found.

7.7 COUNTER MACHINE

Counter machine has the same structure as the multistack machine, but in place of each stack is a counter. Counters hold any non negative integer, but we can only distinguish between zero and non zero counters.

Counter machines are off - line Turing machines whose storage tapes are semi - infinite, and whose tape alphabets contain only two symbols, Z and B (blank). Furthermore the symbol Z, which serves as a bottom of stack marker, appears initially on the cell scanned by the tape head and may never appear on any other cell. An integer i can be stored by moving the tape head i cells to the right of Z. A stored number can be incremented or decremented by moving the tape head right or left. We can test whether a number is zero by checking whether Z is scanned by the head, but we cannot directly test whether two numbers are equal.

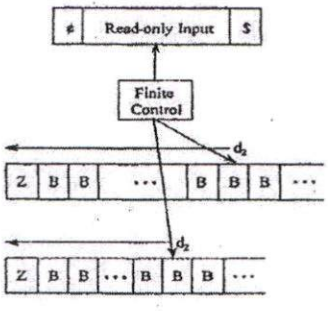

FIGURE : Counter Machine

¢ and $ are customarily used for end markers on the input. Here Z is the non blank symbol on each tape. An instantaneous description of a counter machine can be described by the state, the input tape contents, the position of the input head, and the distance of the storage heads from the symbol Z (shown here as d_1 and d_2). We call these distances the counts on the tapes. The counter machine can only store a count an each tape and tell if that count is zero.

Power of Counter Machines

- Every language accepted by a counter Machine is recursively enumerable.
- Every language accepted by a one - counter machine is a CFL so a one - counter machine is a special case of one - stack machine i. e., a PDA

7.8 TYPES OF TURING MACHINES

Various types of Turing Machines are :

i. With multiple tapes.
ii. With one tape but multiple heads.
iii. With two dimensional tapes.
iv. Non deterministic Turing machines.

It is observed that computationally all these Turing Machines are equally powerful. That means one type can compute the same that other can. However, the efficiency of computation may vary.

1. Turing machine with Two - Way Infinite Tape :

This is a TM that have one finite control and one tape which extends infinitely in both directions.

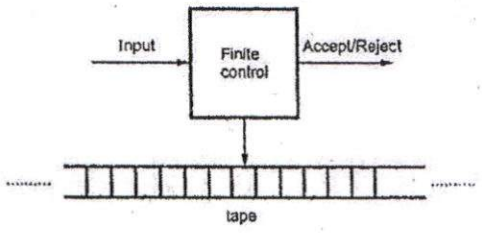

FIGURE : TM with Infinite Tape

It turns out that this type of Turing machines are as powerful as one tape Turing machines whose tape has a left end.

2. Multiple Turing Machines :

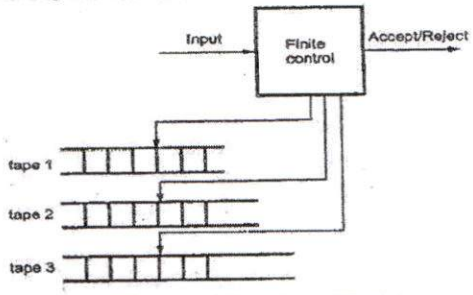

FIGURE : Multiple Turing Machines

A multiple Turing machine consists of a finite control with k tape heads and k tapes, each tape is infinite in both directions. On a single move depending on the state of the finite control and the symbol scanned by each of the tape heads, the machine can

1. Change state.
2. Print a new symbol on each of the cells scanned by its tape heads.
3. Move each of its tape heads, independently, one cell to the left or right or keep it stationary.

Initially, the input appears on the first tape and the other tapes are blank.

3. Nondeterministic Turing Machines :

A nondeterministic Turing machine is a device with a finite control and a single, one way infinite tape. For a given state and tape symbol scanned by the tape head, the machine has a finite number of choices for the next move. Each choice consists of a new state, a tape symbol to print, and a direction of head motion. Note that the non deterministic TM is not permitted to make a move in which the next state is selected from one choice, and the symbol printed and / or direction of head motion are selected from other choices. The non deterministic TM accepts its input if any sequence of choices of moves leads to an accepting state.

As with the finite automaton, the addition of nondeterminism to the Turing machine does not allow the device to accept new languages.

4. Multidimensional Turing Machines :

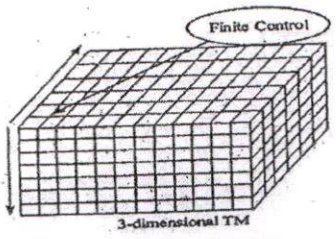

FIGURE : Multidimensional Turing Machine

The multidimensional Turing machine has the usual finite control, but the tape consists of a k - dimensional array of cells infinite in all 2k directions, for some fixed k. Depending on the state and symbol scanned, the device changes state, prints a new symbol, and moves its tape head in one of 2 k directions, either positively or negatively, along one of the k axes. Initially, the input is along one axis, and the head is at the left end of the input.At any time, only a finite number of rows in any dimension contains nonblank symbols, and these rows each have only a finite number of nonblank symbols

5. Multihead Turing Machines :

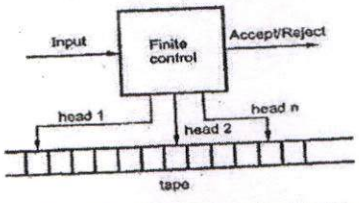

FIGURE : Multihead Turing Machine

A k - head Turing machine has some fixed number, k, of heads. The heads are numbered 1 through k, and a move of the TM depends on the state and on the symbol scanned by each head. In one move, the heads may each move independently left, right or remain stationary.

6. Off - Line Turing Machines :

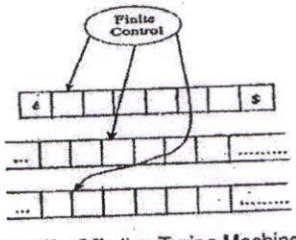

FIGURE : Off - line Turing Machine

COMPUTABILITY THEORY

After going through this chapter, you should be able to understand :

- Chomsky hierarchy of Languages
- Linear Bounded Automata and CSLs
- LR (0) Grammar
- Decidability of problems
- UTM and PCP
- P and NP problems

8.1 CHOMSKY HIERARCHY OF LANGUAGES

Chomsky has classified all grammars in four categories (type 0 to type 3) based on the right hand side forms of the productions.

(a) Type 0

These types of grammars are also known as phrase structured grammars, and RHS of these are free from any restriction. All grammars are type 0 grammars.

Example : productions of types $AS \rightarrow aS$, $SB \rightarrow Sb, S \rightarrow \in$ are type 0 production.

(b) Type 1

We apply some restrictions on type 0 grammars and these restricted grammars are known as type 1 or **context - sensitive grammars** (CSGs). Suppose a type 0 production $\gamma\alpha\delta \rightarrow \gamma\beta\delta$ and the production $\alpha \rightarrow \beta$ is restricted such that $|\alpha| \leq |\beta|$ and $\beta \neq \in$. Then these type of productions is known as type 1 production. If all productions of a grammar are of type 1 production, then grammar is known as type 1 grammar. The language generated by a context - sensitive grammar is called context - sensitive language (CSL).

In CSG, there is left context or right context or both. For example, consider the production $\alpha A\beta \rightarrow \alpha a\beta$. In this, α is left context and β is right context of A and A is the variable which is replaced.

The production of type $S \rightarrow \epsilon$ is allowed in type 1 if ϵ is in L(G), but S should not appear on right hand side of any production.

Example : productions $S \rightarrow AB, S \rightarrow \epsilon, A \rightarrow c$ are type 1 productions, but the production of type $A \rightarrow Sc$ is not allowed. Almost every language can be thought as CSL.

Note : If left or right context is missing then we assume that ϵ is the context.

(c) Type 2

We apply some more restrictions on RHS of type 1 productions and these productions are known as type 2 or context - free productions. A production of the form $\alpha \rightarrow \beta$, where $\alpha, \beta \in (V \cup \Sigma)^*$ is known as type 2 production. A grammar whose productions are type 2 production is known as type 2 or context - free grammar (CFG) and the languages generated by this type of grammars is called context - free languages (CFL).

Example : $S \rightarrow S + S, S \rightarrow S * S, S \rightarrow id$ are type 2 productions.

(d) Type 3

This is the most restricted type. Productions of types $A \rightarrow a$ or $A \rightarrow aB|Ba$, where $A, B \in V$, and $a \in \Sigma$ are known as type 3 or regular grammar productions. A production of type $S \rightarrow \epsilon$ is also allowed, if ϵ is in generated language.

Example : productions $S \rightarrow aS, S \rightarrow a$ are type 3 productions.

Left - linear production : A production of type $A \rightarrow Ba$ is called left - linear production.

Right - linear production : A production of type $A \rightarrow aB$ is called right - linear production. A left - linear or right - linear grammar is called regular grammar. The language generated by a regular grammar is known as regular language.

8.2 LINEAR BOUNDED AUTOMATA

The Linear Bounded Automata (LBA) is a model which was originally developed as a model for actual computers rather than model for computational process. A linear bounded automaton is a restricted form of a non deterministic Turing machine.

A linear bounded automaton is a multitrack Turing machine which has only one tape and this tape is exactly of same length as that of input.

The linear bounded automaton (LBA) accepts the string in the similar manner as that of Turing machine does. For LBA halting means accepting. In LBA computation is restricted to an area bounded by length of the input. This is very much similar to programming environment where size of variable is bounded by its data type.

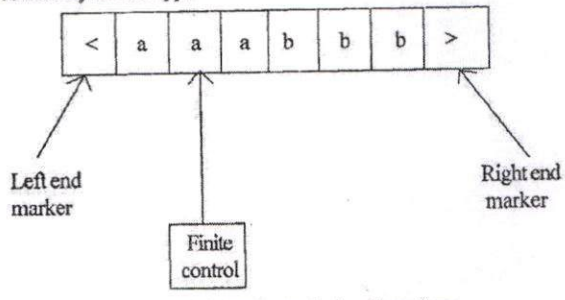

FIGURE : Linear bounded automaton

The LBA is powerful than NPDA but less powerful than Turing machine. The input is placed on the input tape with beginning and end markers. In the above figure the input is bounded by < and >.

A linear bounded automata can be formally defined as :

LBA is 7 - tuple on deterministic Turing machine with

$$M = (Q, \Sigma, \Gamma, \delta, q_0, q_{accept}, q_{reject}) \text{ having}$$

1. Two extra symbols of left end marker and right end marker which are not elements of Γ.
2. The input lies between these end markers.
3. The TM cannot replace < or > with anything else nor move the tape head left of < or right of >.

8.3 CONTEXT SENSITIVE LANGUAGES (CSLs)

The context sensitive languages are the languages which are accepted by linear bounded automata. These type of languages are defined by context sensitive grammar. In this grammar more than one terminal or non terminal symbol may appear on the left hand side of the production rule. Along with it, the context sensitive grammar follows following rules :

i. The number of symbols on the left hand side must not exceed number of symbols on the right hand side.
ii. The rule of the form $A \rightarrow \in$ is not allowed unless A is a start symbol. It does not occur on the right hand side of any rule.

The classic example of context sensitive language is $L = \{a^n\ b^n\ c^n \mid n \geq 1\}$. The context sensitive grammar can be written as :

S	→	aBC
S	→	SABC
CA	→	AC
BA	→	AB
CB	→	BC
aA	→	aa
aB	→	ab
bB	→	bb
bC	→	bc
cC	→	cc

Now to derive the string aabbcc we will start from start symbol :

S	rule S →	SABC
SABC	rule S →	aBC
aBCABC	rule CA →	AC
aBACBC	rule CB →	BC
aBABCC	rule BA →	AB
aABBCC	rule aA →	aa
aaBBCC	rule aB →	ab
aabBCC	rule bB →	bb
aabbCC	rule bC →	bc
aabbcC	rule cC →	cc
aabbcc		

Note : The language $a^n\ b^n\ c^n$ where $n \geq 1$ is represented by context sensitive grammar but it can not be represented by context free grammar.

Every context sensitive language can be represented by LBA.

8.4 LR (k) GRAMMARS

Before going to the topic of LR (k) grammar, let us discuss about some concepts which will be helpful understanding it.

In the unit of context free grammars you have seen that to check whether a particular string is accepted by a particular grammar or not we try to derive that sentence using rightmost derivation or leftmost derivation. If that string is derived we say that it is a valid string.

Example :

$$E \rightarrow E + T \mid T$$
$$T \rightarrow T * F \mid F$$
$$F \rightarrow id \mid (E)$$

Suppose we want to check validity of a string id + id * id . Its rightmost derivation is

$$\begin{aligned} E &\Rightarrow E + T \\ &\Rightarrow E + T * F \\ &\Rightarrow E + T * id \\ &\Rightarrow E + F * id \\ &\Rightarrow E + id * id \\ &\Rightarrow T + id * id \\ &\Rightarrow F + id * id \\ &\Rightarrow id + id * id \end{aligned}$$

FIGURE(a) : Rightmost Derivation of id + id * id

Since this sentence is derivable using the given grammar. It is a valid string. Here we have checked the validity of string using process known as derivation.

In reduction process we have seen that we repeat the process of substitution until we get starting state. But some times several choices may be available for replacement. In this case we have to backtrack and try some other substring . For certain grammars it is possible to carry out the process in deterministic. (i. e., having only one choice at each time). LR grammars form one such subclass of context free grammars. Depending on the number of look ahead symbolized to determine whether a substring must be replaced by a non terminal or not, they are classified as LR(0) , LR(1).... and in general LR(k) grammars.

LR(k) stands for left to right scanning of input string using rightmost derivation in reverse order (we say reverse order because we use reduction which is reverse of derivation) using look ahead of k symbols.

8.4.1 LR(0) Grammar

LR(0) stands for left to right scanning of input string using rightmost derivation in reverse order using 0 look ahead symbols.

Before defining LR(0) grammars, let us know about few terms.

Prefix Property : A language L is said to have prefix property if whenever w in L, no proper prefix of w is in L. By introducing marker symbol we can convert any DCFL to DCFL with prefix property. Hence $L\$ = \{ w\$ \mid w \in L \}$ is a DCFL with prefix property whenever w is in L.

Example : Consider a language L = { cat, cart, bat, art, car } . Here, we can see that sentence cart is in L and its one of the prefixes car is also is in L. Hence, it is not satisfying property. But L$ = { cat $, cart $, bat $, art $, car $ }

Here, cart $ is in L$ but its prefix cart or car are not present in L$. Similarly no proper prefix is present in L$. Hence, it is satisfying prefix property.

Note : LR(0) grammar generates DCFL and every DCFL with prefix property has a LR(0) grammar.

LR Items

An item for a CFG is a production with dot any where in right side including beginning or end. In case of $\in$ production, suppose $A \rightarrow \in$, $A \rightarrow .$ is an item.

Computing Valid Item Sets

The main idea here is to construct from a given grammar a deterministic finite automata to recognize viable prefixes. We group items together into sets which give to states of DFA. The items may be viewed as states of NFA and grouped items may be viewed as states of DFA obtained using subset construction algorithm.

To compute valid set of items we use two operations goto and closure.

Closure Operation

If I is a set of items for a grammar G, then closure (I) is the set of items constructed from I by two rules.

1. Initially, every item I is added to closure (I).
2. If $A \rightarrow \alpha.B\beta$ is in closure (I) and $B \rightarrow \delta$ is production then add item $B \rightarrow \delta$ to I, if it is not already there. We apply this rule until no more new items can be added to closure (I).

Example : For the grammar,

$$S' \rightarrow S$$
$$S \rightarrow cAd$$
$$A \rightarrow a$$

If $S' \rightarrow S$ is set of one item in state I then closure of I is,

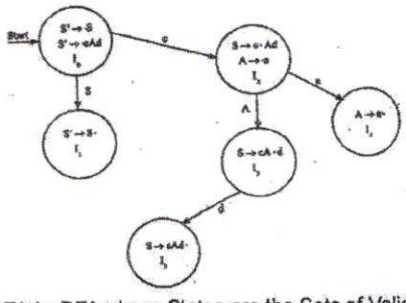
I_i : $S' \rightarrow .s$
$S \rightarrow .cAD$

The first item is added using rule 1 and $S \rightarrow .cAd$ is added using rule 2. Because '.' is followed by nonterminal S we add items having S in LHS. In $S \rightarrow .cAd$ '.' is followed by terminal so no new item is added.

Goto Function : It is written as goto (I, X) where I is set of items and X is grammar symbol.

If $A \rightarrow \alpha.X\beta$ is in some item set I then goto (I, X) will be closure of set of all item $A \rightarrow \alpha.X.\beta$.

DFA :



FIGURE(a) : DFA whose States are the Sets of Valid Items

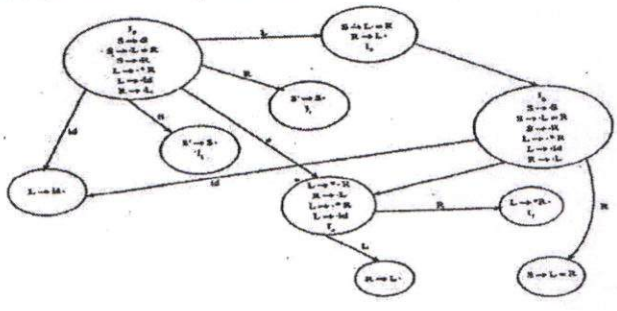
Definition of LR(0) Grammar : We say G is an LR (0) grammar if,

1. Its start symbol does not appear on the right hand side of any production and
2. For every viable prefix γ of G, whenever $A \rightarrow \alpha$ is a complete item valid for γ, then no other complete item nor any item with terminal to the right of the dot is valid for γ.

Condition 1 : For a grammar to be LR(0) it should satisfy both the conditions. The first condition can be made to satisfy by all grammars by introduction of a new production $S' \rightarrow S$ is known augmented grammar.

Condition 2 : For the DFA shown in Figure(a), the second condition is also satisfied because in the item sets I_1, I_4 and I_5 each containing a complete item, there are no other complete items nor any other conflict.

Example : Consider the DFA given in figure(b).



FIGURE(b) : DFA for the given Grammar

Each problem P is a pair consisting of a set and a question, where the question can be applied to each element in the set. The set is called the domain of the problem, and its elements are called the instances of the problem.

Example :

Domain = { All regular languages over some alphabet Σ } ,
Instance : L = { w : w is a word over Σ ending in abb} ,
Question : Is union of two regular languages regular ?

8.5.1 Decidable and Undecidable Problems

A problem is said to be decidable if

1. Its language is recursive, or
2. It has solution

Other problems which do not satisfy the above are undecidable. We restrict the answer of decidable problems to " YES" or "NO" . If there is some algorithm exists for the problem, then outcome of the algorithm is either "YES" or "NO" but not both. Restricting the answers to only "YES" or "NO" we may not be able to cover the whole problems, still we can cover a lot of problems. One question here. Why we are restricting our answers to only "YES" or "NO"? The answer is very simple ; we want the answers as simple as possible.

Now, we say " If for a problem, there exists an algorithm which tells that the answer is either "YES" or "NO" then problem is decidable."

If for a problem both the answers are possible ; some times "YES" and sometimes "NO", then problem is undecidable.

8.5.2 Decidable Problems for FA, Regular Grammars and Regular Languages

Some decidable problems are mentioned below :

1. Does FA accept regular language ?
2. Is the power of NFA and DFA same ?
3. L_1 and L_2 are two regular languages. Are these closed under following :
   (a) Union
   (b) Concatenation
   (c) Intersection
   (d) Complement

6. We have following co - theorem based on above discussion for recursive enumerable and recursive languages.

Let L and $\overline{L}$ are two languages, where $\overline{L}$ the complement of L, then one of the following is true :

(a) Both L and $\overline{L}$ are recursive languages,

(b) Neither L nor $\overline{L}$ is recursive languages,

(c) If L is recursive enumerable but not recursive, then $\overline{L}$ is not recursive enumerable and vice versa.

Undecidable Problems about Turing Machines

In this section, we will first discuss about halting problem in general and then about TM.

Halting Problem (HP)

The **halting problem** is a decision problem which is informally stated as follows :

"Given a description of an algorithm and a description of its initial arguments, determine whether the algorithm, when executed with these arguments, ever halts. The alternative is that a given algorithm runs forever without halting."

Alan Turing proved in 1936 that there is no general method or algorithm which can solve the halting problem for all possible inputs. An algorithm may contain loops which may be infinite or finite in length depending on the input and behaviour of the algorithm. The amount of work done in an algorithm usually depends on the input size. Algorithms may consist of various number of loops, nested or in sequence. The HP asks the question :

Given a program and an input to the program, determine if the program will eventually stop when it is given that input ?

One thing we can do here to find the solution of HP. Let the program run with the given input and if the program stops and we conclude that problem is solved. But, if the program doesn't stop in a reasonable amount of time, we can not conclude that it won't stop. The question is : " how long we can wait .... ?" . The waiting time may be long enough to exhaust whole life. So, we can not take it as easier as it seems to be. We want specific answer, either "YES" or "NO", and hence some algorithm to decide the answer.

Now, we analyse the following :

1. If H outputs "YES" and says that Q halts then Q itself would loop (that's how we constructed it).
2. If H outputs "NO" and says that Q loops then Q outputs "YES" and will halts.

Since , in either case H gives the wrong answer for Q. Therefore, H cannot work in all cases and hence can't answer right for all the inputs. This contradicts our assumption made earlier for HP. Hence, HP is undecidable.

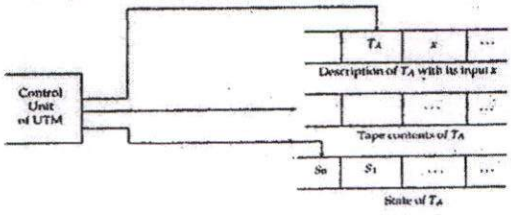
Theorem : HP of TM is undecidable.
Proof : HP of TM means to decide whether or not a TM halts for some input w. We can prove this following the similar steps discussed in above theorem.

8.6 UNIVERSAL TURING MACHINE

The Church - Turing thesis conjectured that anything that can be done on any existing digital computer can also be done by a TM. To prove this conjecture. A. M. Turing was able to construct a single TM which is the theoretical analogue of a general purpose digital computer. This machine is called a Universal Turing Machine (UTM). He showed that the UTM is capable of initiating the operation of any other TM, that is, it is a reprogrammable TM. We can define this machine in more formal way as follows :

Definition : A Universal Turing Machine (denoted as UTM) is a TM that can take as input an arbitrary TM T_A with an arbitrary input for T_A and then perform the execution of T_A on its input.

What Turing thus showed that a single TM can acts like a general purpose computer that stores a program and its data in memory and then executes the program. We can describe UTM as a 3 - tape TM where the description of TM, T_A and its input string $x \in A^*$ are stored initially on the first tape, t_1. The second tape, t_2 used to hold the simulated tape of T_A, using the same format as used for describing the TM, T_A. The third tape, t_3 holds the state of T_A



Now, suppose that a Turing machine, T_A, is consisting of a finite number of configurations, denoted by, $c_0, c_1, c_2, \ldots, c_p$ and let $\overline{c}_0, \overline{c}_1, \overline{c}_2, \ldots, \overline{c}_p$ represent the encoding of them. Then, we can define the encoding of T_A as follows :

$$* \overline{c}_0 \# \overline{c}_1 \# \overline{c}_2 \# \ldots\ldots \# \overline{c}_p *$$

Here, * and # are used only as separators, and cannot appear elsewhere. We use a pair of *'s to enclose the encoding of each configuration of TM, T_A.

The case where $\delta(s,a)$ is undefined can be encoded as follows :

$$\# \overline{s}\ 0\overline{a}\ 0\overline{B}\ \#$$

where the symbols $\overline{s}$, $\overline{a}$ and $\overline{B}$ stand for the encoding of symbols, s , a and B (Blank character), respectively.

Working of UTM

Given a description of a TM, T_A and its inputs representation on the UTM tape, t_1 and the starting symbol on tape , t_3, the UTM starts executing the quintuples of the encoded TM as follows :

1. The UTM gets the current state from tape, t_3 and the current input symbol from tape t_2.
2. then, it matches the current state - symbol pair to the state symbol pairs in the program listed on tape, t_1.
3. if no match occurs, the UTM halts, otherwise it copies the next state into the current state cell of tape, t_3, and perform the corresponding write and move operations on tape, t_2.
4. if the current state on tape, t_3 is the halt state, then the UTM halts, otherwise the UTM goes back to step 2.

8.7 POST'S CORRESPONDENCE PROBLEM (PCP)

Post's correspondence problem is a combinatorial problem formulated by Emil Post in 1946. This problem has many applications in the field theory of formal languages.

Definition :

A correspondence system P is a finite set of ordered pairs of nonempty strings over some alphabet.

Here, $u_1 = b,\ u_2 = a,\ u_3 = abc,\ v_1 = ca,\ v_2 = ab,\ v_3 = c$.

We have a solution $w = u_3\ u_2 = \ v_2\ v_1 = abca$.

8.8 TURING REDUCIBILITY

Reduction is a technique in which if a problem A is reduced to problem B then any solution of B solves A. In general, if we have an algorithm to convert some instance of problem A to some instance of problem B that have the same answer then it is called A reduces to B.

FIGURE: Reduction

Definition : Let A and B be the two sets such that $A, B \subseteq N$ of natural numbers. Then A is Turing reducible to B and denoted as $A \leq_T B$.

If there is an oracle machine that computes the characteristic function of A when it is executed with oracle machine for B.

This is also called as A is B - recursive and B - computable. The oracle machine is an abstract machine used to study decision problem. It is also called as **Turing machine** with **black box.**

We say that A is Turing equivalent to B and write $A \equiv_T B$ if $A \leq_T B$ and $B \leq_T A$.

Properties :

1. Every set is Turing equivalent to its complement.
2. Every computable set is Turing equivalent to every other computable set.
3. If $A \leq_T B$ and $B \leq_T C$ then $A \leq_T B$.

8.9 DEFINITION OF P AND NP PROBLEMS

A problem is said to be solvable if it has an algorithm to solve it. Problems can be categorized into two groups depending on time taken for their execution.

1. The problems whose solution times are bounded by polynomials of small degree. **Example:** bubble sort algorithm obtains n numbers in sorted order in polynomial time $P(n) = n^2 - 2n + 1$ where n is the length of input. Hence, it comes under this group.

2. Second group is made up of problems whose best known algorithm are non polynomial example, travelling salesman problem has complexity of $O(n^2\ 2^n)$ which is exponential. Hence, it comes under this group.

A problem can be solved if there is an algorithm to solve the given problem and time required is expressed as a polynomial p(n), n being length of input string. The problems of first group are of this kind.

The problems of second group require large amount of time to execute and even require moderate size so these problems are difficult to solve. Hence, problems of first kind are tractable or easy and problems of second kind are intractable or hard.

8.9.1 P - Problem

P stands for deterministic polynomial time. A deterministic machine at each time executes an instruction. Depending on instruction, it then goes to next state which is unique.

Hence, time complexity of deterministic TM is the maximum number of moves made by M is processing any input string of length n, taken over all inputs of length n.

Definition : A language L is said to be in class P if there exists a (deterministic) TM M such that M is of time complexity P(n) for some polynomial P and M accepts L.
Class P consists of those problem that are solvable in polynomial time by DTM.

8.9.2 NP - Problem

NP stands for nondeterministic polynomial time.

The class NP consists of those problems that are verifiable in polynomial time. What we mean here is that if we are given certificate of a solution then we can verify that the certificate is correct in polynomial time in size of input problem.

8.10 NP - COMPLETE AND NP - HARD PROBLEMS

A problem S is said to be NP- Complete problem if it satisfies the following two conditions.

1. $S \in NP$, and
2. For every other problems $S_i \in NP$ for some $i = 1, 2, n$, there is polynomial - time transformation from S_i *to* S i.e. every problem in NP class polynomial - time reducible to S.

We conclude one thing here that if S_i is NP - complete then S is also NP - Complete.

As a consequence, if we could find a polynomial time algorithm for S, then we can solve all NP problems in polynomial time, because all problems in NP class are polynomial - time reducible to each other.

"A problem P is said to be NP - Hard if it satisfies the second condition as NP - Complete, but not necessarily the first condition.".

The notion of NP - hardness plays an important role in the discussion about the relationship between the complexity classes P and NP. It is also often used to define the complexity class NP - Complete which is the intersection of NP and NP - Hard. Consequently, the class NP - Hard can be understood as the class of problems that are NP - complete or harder.

Example : An NP - Hard problem is the decision problem SUBSET - SUM which is as follows.

" Given a set of integers, do any non empty subset of them add up to zero? This is a yes / no question, and happens to be NP - complete ".

There are also decision problems that are NP - Hard but not NP - Complete , for example, the halting problem of Turing machine. It is easy to prove that the halting problem is NP - Hard but not NP - Complete. It is also easy to see that halting problem is not in NP since all problems in NP are decidable but the halting problem is not (voilating the condition first given for NP - complete languages).

In Complexity theory, the **NP - complete** problems are the hardest problems in NP class, in the sense that they are the ones most likely not to be in P class. The reason is that if we could find a way to solve any NP - complete problem quickly, then you could use that algorithm to solve all NP problems quickly.

At present time, all known algorithms for NP - complete problems require time which is exponential in the input size. It is unknown whether there are any faster algorithms for these are not.

CMR COLLEGE OF ENGINEERING & TECHNOLOGY

(UGC AUTONOMOUS)

B.Tech V Semester Supplementary Examinations May-2023

Course Name: FORMAL LANGUAGES & AUTOMATA THEORY

(Computer Science & Engineering)

Date: 11.05.2023 AN **Time: 3 hours** **Max.Marks: 70**

(Note: Assume suitable data if necessary)

PART-A

Answer all TEN questions (Compulsory)

Each question carries TWO marks. **10x2=20M**

1. Define Non-deterministic Finite Automata. 2 M
2. Define Moore Machine. 2 M
3. Construct a regular grammar for L= $\{0^n 1 / n>=1\}$ 2 M
4. Build the simplified regular expression for the following regular expression r (r*r + r*) + r*? 2 M
5. Define Context Free Grammar. 2 M
6. Define Push Down Automata. 2 M
7. Describe the applications of the pumping lemma. 2 M
8. Discuss about the various representations of Turing Machines. 2 M
9. Justify with an example of undecidable problem. 2 M
10. Compare recursive and recursive enumerable languages. 2 M

PART-B

Answer the following. Each question carries TEN Marks. **5x10=50M**

11.A). Construct NFA with ε which accepts for 0* 1* 2*. And convert into NFA without ε transitions. 10M

OR

11. B). i) Explain the procedure for converting DFA to NFA. 5M
ii) Briefly discuss about Finite Automata with Epsilon- Transitions. 5M

12. A). i) Define Regular Expression? Explain about the Properties of Regular Expressions. 5M
ii) Construct a DFA for the Regular Language consisting of even number of a's and b's. 5M

OR

12. B). i) Prove that regular set $L=\{1^p / p \text{ is a prime}\}$ is not regular. 5M
ii) Explain about Pumping Lemma. 5M

13. A). i) Define Ambiguous Grammar. Demonstrate whether the grammar. S->aAB, A->bC/cd, C->cd, B->c/d Is Ambiguous or not? 5M
ii) Construct a PDA for the following grammar S->AA/a, A->SA/b. 5M

OR

13. B). Construct a PDA that accepts the language $L = \{ WCW^R \mid W \in (a+b)^* \}$ 10M

(P.T.O..)

14. A). i) Find GNF for S->AB, A->BS/b , B->SA/a. 5M
ii) Design a Turing Machine for $L=\{0^n 1^n | n>=1\}$ 5M

OR

14. B). Design a Turing Machine to accept $L=\{WCW^R | W \text{ is in } (a+b)^*\}$. 10M

15. A). i) Explain Decision Properties of Context-Free Languages. 5M
ii) Explain the concepts of Undecidable Problems about Turing Machines. 5M

OR

15. B). i) Outline an overview of recursively enumerable language. 5M
ii) Outline the correspondence between P, NP and NP-complete problems. 5M

CMR COLLEGE OF ENGINEERING & TECHNOLOGY

(UGC AUTONOMOUS)

B.Tech V Semester Regular/Supplementary Examinations December-2022

Course Name: FORMAL LANGUAGES & AUTOMATA THEORY

(Computer Science & Engineering)

Date: 07.12.2022 AN Time: 3 hours Max.Marks: 70

(Note: Assume suitable data if necessary)

PART-A

Answer all TEN questions (Compulsory)

Each question carries TWO marks. 10x2=20M

1. Differentiate between NFA and DFA. 2 M
2. Distinguish between Moore and Mealy machines. 2 M
3. State Arden's theorem. 2 M
4. List out the Applications of Regular Expressions. 2 M
5. Give CFG for the language that contains strings of all palindromes. 2 M
6. What is the difference between Finite Automata and PDA? 2 M
7. State Pumping Lemma for CFL. 2 M
8. Design Turing machine to find complement of a given binary number. 2 M
9. Draw the block diagram of Turing machine. 2 M
10. Discuss about recursive languages. 2 M

PART-B

Answer the following. Each question carries TEN Marks. 5x10=50M

11.A). i) Construct a Mealy Machine to find 2's complement of a given binary number. 5M

ii) Obtain DFA to accept strings having 5M

a) Exactly one a

b) atleast one 'a'

c) Not more than 3 a's

OR

11. B). Design an NFA the set of all strings over {a, b} with three consecutive b's and constructs its equivalent DFA. 10M

12. A). i) State whether the following language is regular or not $L = \{a^i b^i \mid i >= 1\}$. 5M

ii) Write the regular expression representing the set of all strings over {a, b} with three consecutive b's? 5M

OR

12. B). Construct an NFA with Ɛ-moves for the regular expression (Show Intermediate Steps Also) 10M

(a+b)*(aa+bb)(a+b)*

13. A). Describe about Ambiguity in CFG with a suitable example. 10M

OR

13. B). Construct PDA for the language $L=\{a^n b^{2n} \mid n >= 1\}$. 10M

(P.T.O..)

14. A). i) Convert the following grammar to CNF. 5M
S->cBA, A->aA/a, B->bB/b

ii) Minimize the following CFG. 5M
S->A/0C1, A->B/01/10,C->0/CD

OR

14. B). Design a Turing machine to accept palindromes. Example L = { abba}. 10M

15. A). Explain the following terms in brief: 10M
i) Types of Turing Machines
ii) P and NP problem
iii) Church's Hypothesis.

OR

15. B). i) Define PCP explain PCP with an example. 7M

ii) Describe the properties of Recursively enumerable languages. 3M
